**Cobalt(II) Complexes of 13,14-Diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradecane-3,5,9,11-tetraene (3f).** The general procedure was to heat under reflux for 30 min a mixture of the cobalt(II) salt (5–10 mmoles), ethanol (50 ml), and diamine 3f (1.86 g, 10 mmoles). After cooling to 25°, the precipitated complex was filtered, rinsed with chloroform, and dried at 25–100° (0.1 mm). The insolubility of these complexes in common organic solvents precluded the measurement of solution ultraviolet or nuclear magnetic resonance spectra. In the donor solvents water, dimethylformamide, and dimethyl sulfoxide, these complexes dissolved with decomposition.

(a) Cobalt(II) chloride hexahydrate formed a blue powder in 90% yield, mp >300° dec;  $\nu_{\text{max}}^{\text{KBr}}$  3450, 3200 (NH), 3030, and 1625 cm<sup>-1</sup> (CH=CH);  $\mu$  = 4.54 BM.<sup>30</sup>

(30) The magnetic susceptibility of the four compounds at 297°K was independent of field from 18 to kgauss. Diamagnetic contributions were calculated from Pascal's constants.

**Reaction of 13,14-Diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradecane (4a) with Cobalt(II) Chloride.** A mixture of cobalt(II) chloride hexahydrate (1.0 g), ethanol (50 ml), and diamine 4a (1.60 g) was heated under reflux for 24 hr, cooled, and filtered free of cobalt(II) chloride (0.40 g). Evaporation of the filtrate left a solid (1.71 g) from which 0.40 g of unreacted diamine was sublimed at 70° (0.1 mm). The residue (1.30 g) was recrystallized twice from a mixture of ethanol (10 ml) and acetone (20 ml) to produce colorless needles of 13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradecane monohydrochloride (0.55 g), mp 270–280° dec; no  $\lambda_{\text{max}}^{\text{EtOH}}$  208–400 m $\mu$ ;  $\nu_{\text{max}}^{\text{KBr}}$  1590 cm<sup>-1</sup> (NH<sub>2</sub><sup>+</sup>); nmr (CDCl<sub>3</sub>)  $\tau$  6.79 (4 protons) and 8.07 (16 protons).

**Anal.** Calcd for C<sub>12</sub>H<sub>13</sub>N<sub>2</sub>Cl: C, 62.44; H, 10.05; N, 12.14; Cl, 15.37. Found: C, 62.63; H, 9.71; N, 11.86; Cl, 15.75.

**13,14-Dimethyl-13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradeca-3,5,9,11-tetraene Monomethiodide (10) Method a.** A mixture of 13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradeca-3,5,9,11-tetraene (3f) (18.6 g, 0.10 mole), methanol (200 ml), anhydrous sodium carbonate (15.9 g, 0.15 mole), and methyl iodide (31 ml, 0.50 mole) was heated under reflux for 24 hr. After evaporation to dryness, the residue was stirred with ice-water (50 ml) and filtered. The residue was recrystallized from acetonitrile (500 ml), yield 27.77 g (78%) of monomethiodide.

**Method b.** A mixture of 13,14-dimethyl-13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradeca-3,5,9,11-tetraene (3c) (3.0 g), acetonitrile (15 ml), and methyl iodide (15 ml) was heated overnight in a sealed tube at 100°. Evaporation of the mixture produced 4.44 g (89%) of the monoquaternary iodide. The analytical sample was recrystallized twice from acetonitrile as white crystals, mp 300–302° dec;  $\nu_{\text{max}}^{\text{KBr}}$  3110, 3085, 3020 (CH=CH), 2970, 2935, 2890, 2870, 2830, and 2790 cm<sup>-1</sup> (CH, NCH<sub>2</sub>).

**Anal.** Calcd for C<sub>14</sub>H<sub>21</sub>N<sub>2</sub>I: C, 50.58; H, 5.94; N, 7.87. Found: C, 50.62, 50.41; H, 5.80, 5.63; N, 8.01, 7.84.

**13,14-Dimethyl-13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradecane Monomethiodide (11).** Application of method a above with 4a produced only the dimethyl compound 4c. Method b above with 4c produced an 84% yield of the desired monomethiodide after recrystallization from ethanol. Two further recrystallizations from ethanol produced long colorless needles of 11, mp 246–248° dec;  $\nu_{\text{max}}^{\text{KBr}}$  2960–2790 and 1470 cm<sup>-1</sup> (CH, NCH<sub>2</sub>); nmr (CDCl<sub>3</sub>)  $\tau$  6.37 (multiplet, two tertiary protons), 6.57 (singlet, three axial NCH<sub>2</sub> protons), 6.65 (singlet, three equatorial NCH<sub>2</sub> protons), 6.80 (multiplet, two tertiary protons), 7.15 (singlet, three tertiary NCH<sub>2</sub> protons), and 7.50–8.33 (broad multiplet, 16 CH<sub>2</sub> protons).

**Anal.** Calcd for C<sub>16</sub>H<sub>23</sub>N<sub>2</sub>I: N, 7.52; I, 34.83. Found: N, 7.60, 7.61; I, 35.64.

**Hofmann Elimination on 13,14-Dimethyl-13,14-diazatricyclo[6.4.1.1<sup>3,7</sup>]tetradeca-3,5,9,11-tetraene Monomethiodide (10).** 1. A mixture of the monomethiodide 10 (7.29 g), water (50 ml), methanol (275 ml), and freshly prepared silver oxide (from 10 g of silver nitrate) was stirred at room temperature overnight. The silver salts were filtered, washed with methanol, and air dried (yield 9.55 g, theory). Evaporation of the filtrate left a brown viscous residue which was heated at 120° (0.1 mm) for 30 min, then distilled in a short-path still at 120° (0.1 mm). Redistillation produced the Hofmann product 12 as a pale yellow oil (4.29 g, 92%) from which the color was removed completely after one further distillation. The

unstable distillate crystallized on cooling to -78°. The crystalline dimethylamino-N-methylazatricyclo[6.4.1.1<sup>3,7</sup>]tetradeca-3,5,9,11-tetraene (12) had mp 43–44°;  $\lambda_{\text{max}}^{\text{CH}_2\text{OH}}$  250 m $\mu$  ( $\epsilon$  9700);  $\nu_{\text{max}}^{\text{CCl}_4}$  3040, 3020 (CH=CH), and 1470 cm<sup>-1</sup> (NCH<sub>2</sub>); nmr (CDCl<sub>3</sub>)  $\tau$  4.14–4.32 (complex multiplet, eight vinyl protons), 6.53 (multiplet, one tertiary proton), 7.12 (doublet,  $J$  = 4 cps, two tertiary protons), 7.62 (singlet, six N(CH<sub>2</sub>)<sub>2</sub> protons), and 7.75 (singlet, three NCH<sub>2</sub> protons).

**Anal.** Calcd for C<sub>14</sub>H<sub>23</sub>N<sub>2</sub>: C, 78.90; H, 8.83; N, 12.27; mol wt, 228. Found: C, 78.39; 78.31; H, 8.75, 8.92; N, 12.01; mol wt, 228.

2. A solution of the Hofmann product 12 (8.38 g) in acetonitrile (150 ml) was treated dropwise with methyl iodide (30 ml) and stirred overnight at 25°. The crude crystalline bismethiodide (5.01 g, 26%) was filtered. Two recrystallizations of 1.45 g of this product from water (25 ml) and acetone (300 ml) with Darco G-60 treatment produced 0.92 g of the white crystalline bismethiodide of 12, mp 160–165° dec;  $\lambda_{\text{max}}^{\text{EtOH}}$  260 m $\mu$  (sh,  $\epsilon$  8000), 227 m $\mu$  ( $\epsilon$  28,800);  $\nu_{\text{max}}^{\text{KBr}}$  3080, 3050, 3025, 3010 (CH=CH), 1485, 1460, 1440, and 1410 cm<sup>-1</sup> (NCH<sub>2</sub>); nmr (CF<sub>3</sub>CO<sub>2</sub>H)  $\tau$  3.45–4.28 (complex multiplet, eight vinyl protons), 4.64 (triplet,  $J$  = 7 cps, two tertiary protons), 5.73 (multiplet, one tertiary proton), 6.55 (singlet, 12 NCH<sub>2</sub> protons), and 6.82 (singlet, three NCH<sub>2</sub> protons).

**Anal.** Calcd for C<sub>17</sub>H<sub>25</sub>N<sub>2</sub>I<sub>2</sub>: C, 39.86; H, 5.12; N, 5.47. Found: C, 40.15; H, 4.99; N, 5.54.

Evaporation of the mother liquors from this reaction left a dark intractable gum.

3. A further Hofmann degradation on 2.45 g of the bismethiodide of 12 with the silver oxide from 3 g of silver nitrate in water (20 ml) and methanol (30 ml) produced 3.23 g of silver salts (theory 3.19 g) and a gummy residue which formed a brown oily distillate at 180° (0.1 mm). Redistillation produced 0.06 g of a yellow unstable oil which appeared to consist of several products. Addition of 10% hydrochloric acid to the pump trap followed by evaporation produced 0.42 g (1 molar ratio) of trimethylamine hydrochloride, identified by conversion to trimethylammonium picrate, mp 215–217° dec (lit.<sup>31</sup> mp 216°).

# Mechanisms of Photochemical Reactions in Solution. XLIII.<sup>1</sup> Addition of Maleic Anhydride to Benzene

William M. Hardham and George S. Hammond

Contribution No. 3313 from the Gates and Crellin Laboratories of Chemistry,  
California Institute of Technology, Pasadena, California 91109.

Received August 29, 1966

**Abstract:** The photoaddition of maleic anhydride to benzene by both direct and sensitized excitation has been studied. Use of suitable quenchers and sensitizers and variation of the concentration of the reactants indicate that a triplet mechanism obtains. Key steps in the mechanism are: (1) excitation of the maleic anhydride–benzene complex to its triplet state, (2) collapse of the excited complex to a monoadduct, and (3) reaction of the first adduct with maleic anhydride in a thermal reaction. Study of quenching reactivities indicates that the triplet excitation energy of the maleic anhydride–benzene complex is at least 2 kcal/mole less than the excitation energy of maleic anhydride.

The photochemical addition of maleic anhydride to benzene was discovered almost simultaneously by three groups of workers.<sup>2–4</sup>

Schenck and Steinmetz<sup>2</sup> showed that the reaction could be conveniently carried out using benzophenone as a sensitizer and Bryce-Smith and Lodge<sup>3</sup> made a preliminary comparison of the sensitized and unsensitized reactions. Both groups suggested that the mechanisms of the direct and indirect reactions are distinctly different. Furthermore, the English workers reported some very unusual characteristics of the reactions<sup>3</sup> although one very important observation has since been reported by the same group<sup>6</sup> to have been in error. We should point out that quantitative studies of the reaction, including our own, have depended upon isolation of 1 which crystallizes from the reaction mixtures. Crystallization is slow and any isolated, negative result may be attributed to supersaturation.

Because of the complexity of the reaction and the provocative nature of the first suggestions concerning mechanism, we felt that the process deserved detailed study. A preliminary report of part of our results has already been published.<sup>7</sup>

## Results and Discussion

Samples were irradiated in ampoules made from thin-walled Pyrex culture tubes in a merry-go-round ap-

paratus<sup>8</sup> so that a number of samples, including actinometric samples, could be irradiated simultaneously. The light source was a 450-w, medium-pressure mercury lamp. The 3130-, 3660-, and 4045-Å lines from the source are transmitted to the extent of 78, 87, and 90% by the Pyrex tubes. In most experiments with sensitizers a uranium glass filter was used, eliminating essentially all source lines of wavelength shorter than 3300 Å. Some measurements of quantum yields were made using a collimated beam from a high-pressure arc (Westinghouse SAH 800-C)<sup>9</sup> with glass filters chosen to isolate the 3660-Å line. The reaction was monitored by isolating and weighing the insoluble product, 1.

**Sensitizers and Inhibitors.** A survey of potential sensitizers was carried out, giving the results shown in Table I. The yields, given in milligrams, were determined at relatively low conversions (10 mg  $\cong$  2%) using 1.0 M maleic anhydride in benzene. The yields are not necessarily proportional to quantum yields since no corrections have been made for variation in either intersystem crossing efficiencies or variation in the absorption spectra of the additives. Although the experiments with compounds listed as "inhibitors" were not pursued exhaustively, there seems to be a clear-cut difference between these compounds and the effective sensitizers. None of the addition compound was formed even when the uranium glass filter was removed. Obviously the "inhibitors" not only fail to sensitize the reaction but also interfere with the unsensitized reaction. No attempt has been made to quantitatively dissect the effects into quenching and internal light filtering. Concentrations of the additives were adjusted so as to absorb essentially all incident light at 3660 Å, where the benzene–maleic anhydride complex does not absorb. In the experiments with the uranium glass filter, 1–20% of the total incident light was estimated to be absorbed by the complex.

Separation of the sensitizers and inhibitors on the basis of triplet excitation energies is almost, but not quite, perfect. There seems to be a cutoff point with

<sup>a</sup> 1.0 *M* maleic anhydride in benzene, irradiation for 50 hr in a merry-go-round apparatus (outside ring). <sup>b</sup> W. G. Herkstroeter, A. Lamola, and G. S. Hammond, *J. Am. Chem. Soc.*, **86**, 4537 (1964). <sup>c</sup> All reported results with uranium glass filter. <sup>d</sup> Results reported were obtained without uranium glass filter.

sensitizers having about 66-kcal/mole excitation energy; those having higher excitation energies sensitize the reaction and those having less available energy do not. When energy transfer becomes insignificant, the rate of the process must fall below the first-order rate of decay of the sensitizer triplets. From our estimates of the concentrations of the complex (*vide infra*), the lifetimes of the various triplets in solution, and data from flash kinetic studies of triplet quenching,<sup>10-13</sup> we infer that energy transfer must be several kilocalories per mole endothermic at the cutoff point. The apparent anomalies with *p*-cyanobenzophenone and triphenylene may not be significant. Measurement of triplet excitation energies is not highly precise and we have observed other apparently deviant behavior with triphenylene.<sup>13</sup>

**Triplet Excitation Energy of Maleic Anhydride.** The emission spectra from MCIP (5:1 methylcyclohexane-isopentane) glasses containing approximately 10<sup>-3</sup> *M* maleic anhydride were measured at 77°K. A very weak, long-lived emission was observed. After subtraction of the background emission from the solvent the spectrum shown in Figure 1 was obtained. The spectrum was not very reproducible and that shown is the strongest obtained. Although other details varied, the first maximum (at 3980 Å) was reproducible.<sup>14</sup> This indicates that the phosphorescent state has

Figure 1. Emission spectrum of maleic anhydride in MCIP glass at 77°K. Weak emission from the glass has been subtracted.

an excitation energy of about 72 kcal/mole. Addition of benzene in amounts slightly greater than molar equivalence to the maleic anhydride led to complete disappearance of the phosphorescence. Apparently formation of the complex provides faster modes of decay for maleic anhydride triplets than are available to the uncomplexed molecule. The extent to which this is associated with the chemical reaction is not entirely clear.

The absorption spectrum of a 0.067 *M* solution of maleic anhydride in ethyl iodide was measured in a 1-cm cell. The long wavelength spectrum shown in Figure 2 was obtained. The spectrum is probably due to a singlet-triplet transition induced by the external heavy-atom effect.<sup>15</sup> Although the spectrum is ab-

Figure 2. Long wavelength absorption spectrum of maleic anhydride in ethyl iodide solution.

solutely featureless, it is entirely possible that the long wavelength limit occurs close to 3900 Å, the apparent position of the 0-0 band in the phosphorescence spectrum. If anything the absorption spectrum indicates a slightly higher value of the  $S_0 \rightarrow T_1$  excitation energy.

**Quenching of Triplets by Maleic Anhydride.** The reaction of benzophenone with benzhydrol was used to

(14) Factors known to effect the quality of a recorded spectrum are: (1) the purity of the constituents of the solvent, (2) variation in the amount of cracking in the glass, and (3) the phototube. The spectrum shown was the only one recorded with our best phototube.

measure the relative efficiency of maleic anhydride as a quencher for benzophenone triplets.<sup>9,16</sup> The spectroscopic studies reported above indicate that the excitation energy of maleic anhydride is too high to allow it to be a good quencher for benzophenone. However, an earlier measurement,<sup>16</sup> made in the course of a general survey, indicated that maleic anhydride is a good quencher in benzene solution. The study has been repeated in benzene and in nonaromatic solvents. The measurements in benzene are complicated by virtue of the fact that the addition reaction decreases the concentration of the quencher during the course of the runs. Correction for the change in concentration was made using data for the quantum yields of the addition reaction (*vide infra*). The results are shown in Table II.

			Av	65

<sup>a</sup> Benzophenone was initially 0.100 M in each experiment. <sup>b</sup> The benzophenone-benzhydryl reaction without added quencher was used as an actinometer. The parameters reported in ref 18 were used in the calculations. <sup>c</sup> The average concentration of maleic anhydride was approximately 5% lower than the initial concentration in each run; k<sub>q</sub> is the rate constant for quenching of benzophenone triplets by maleic anhydride and k<sub>r</sub> is the rate constant for reaction of benzophenone triplets with benzhydryl.

The quenching reaction was also studied in carbon tetrachloride solution and a solvent consisting of 95% cyclohexane and 5% acetone. The values of k<sub>d</sub>/k<sub>r</sub><sup>17</sup> were redetermined in each medium using Foss's method.<sup>18</sup> The value in cyclohexane-acetone was 0.036, well within experimental error of the value (0.033) for benzene solution; consequently, we infer that hydrogen abstraction from the solvent is unimportant in the former case. In carbon tetrachloride the value was 0.0526. While we have no way of dissecting the ratio, the increase is probably to be associated with an external heavy-atom effect on the radiationless decay rate in carbon tetrachloride. Adventitious quenchers could also be responsible. The quenching constants for maleic anhydride were too small for accurate measurement in both the nonaromatic solvents. In carbon tetrachloride the apparent values ranged from 1 to 9.6 with an average value of 5 ± 5. In cyclohexane-acetone the value was 8 ± 5. In the latter medium there can be no doubt that the quenching activity is real, but of an order of magnitude smaller than the activity in benzene.

The results are neatly accommodated by the hypothesis that the effective quencher in benzene solution is

the benzene-maleic anhydride complex.<sup>19,20</sup> Attempts were made to use the data of Andrews and Keefer<sup>19</sup> for benzene-chloroform mixtures to evaluate the fraction of the anhydride that is in complexed form in neat benzene. The ultraviolet spectra of 1 × 10<sup>-3</sup> and 2 × 10<sup>-3</sup> M solutions indicated 42.5 and 51.0% complex, respectively, if the reported value of ε<sub>2700</sub> for the complex is used. On the other hand, use of the reported equilibrium constant indicates that the anhydride should be 88% complexed. If the absorbance of the solutions at 2700 Å is taken as a measure of the amount of complex, the value of k<sub>q</sub>/k<sub>r</sub> for that species is about 130, a factor of 5 smaller than the largest constants that have been measured.<sup>9,16</sup> If the value of k<sub>d</sub> reported by Bell and Linschitz<sup>21</sup> is used as a reference point, the value of k<sub>q</sub> for the complex is calculated to be 4 × 10<sup>6</sup> l. mole<sup>-1</sup> sec<sup>-1</sup>.

As an ancillary study we measured the reactivity of maleic anhydride as a quencher for acetophenone triplets which have more available excitation energy than benzophenone triplets (73.6 vs. 68.5 kcal/mole). The photoreduction of acetophenone by isopropyl alcohol<sup>22,23</sup> was used as a reference system. The reaction was carried out in cyclohexane. The quenching constant, k<sub>q</sub>/k<sub>r</sub>, for maleic anhydride was evaluated by standard procedures. The results scattered more than is usual but the average value was 193 ± 78. The fact that maleic anhydride in an aliphatic solvent is a good quencher for acetophenone triplets is clear from inspection of any of the experiments. This is in agreement with the assignment of the excitation energy of the uncomplexed anhydride as 72 kcal/mole.

The quenching experiments indicate that the excitation energy of the complex is close to that of benzophenone (68 kcal), about 4 kcal lower than that of the uncomplexed anhydride. This indicates that the binding energy of the complex is greater in the excited state than in the ground state. The triplet excitation is probably partly delocalized between the two partners in the complex. Chemical intuition indicates that charge transfer is probably not a principal factor in stabilization of the excited state since the complex excitation is probably much more closely related to excitation of the acceptor (maleic anhydride) than to that of the donor (benzene). Delocalization of singlet excitation in symmetrical systems has recently been discussed extensively in connection with excimer fluorescence.<sup>24</sup>

**Quantum Yields.** Preliminary measurements showed that quantum yields in the sensitized reaction increased with increasing maleic anhydride concentration in benzene solution. A series of carefully matched runs were then carried out, giving the results shown in Table III. The results are reported in terms of milligrams of product since measurement of relative quantum yields is more accurate than measurement of absolute quantum yields. Actinometric measurements indicate that the highest quantum yields are approximately 0.1.

<sup>a</sup> Milliliter samples irradiated using the uranium glass filter pyro-go-round apparatus. <sup>b</sup> Concentrations chosen to be 0.05 M. <sup>c</sup> Samples having the same run number were irradiated at the same time. Irradiation was continued until the sample was separated from tubes containing 0.05 M anhydride to facilitate weighing. The results given are averages of triplicate.

Results, especially in experiments with the higher concentrations of maleic anhydride, are frustratingly inconsistent. A number of factors may contribute, including the position of the crystalline product and scattering of light by crystals deposited on the walls of the tubes. A major source of error must arise from reasons independent of the light intensity delivered to the sample since there were significant variations in the amount of product collected from duplicate samples in the same run. However, the general trend of the results is reproducible. The yields increase with increasing maleic anhydride concentration up to about 0.25 M and then become constant within experimental error. Absorbance by the different sensitizers was measured at 3660 Å and concentrations were high enough to give essentially complete absorption at that wavelength, although there is some difference in the absorption of the weaker source lines between 3700 and 3800 Å absorbed by the three sensitizers. The data in Table I show that there is only a small dependence of quantum yield on sensitizer concentration, indicating that energy transfer is close to quantitative and that intersystem crossing is not appreciably reversible.

## Variation in Yield as a Function of Maleic Anhydride Concentration<sup>a</sup>

Sensitizer <sup>b</sup> , M	Yield of adduct <sup>c</sup>
0.03	24.9 ± 1.2
0.06	24.2 ± 1.2
0.10	25.4 ± 1.2
0.15	26.1 ± 1.3
0.20	28.3 ± 1.3
0.30	29.1 ± 1.3

<sup>a</sup> Initial concentration of maleic anhydride was 1.00 M in all experiments. <sup>b</sup> Milligrams of product formed by irradiation of 4-ml samples described in the Experimental Section for 8 hr.

Reduction of the light intensity was accomplished by placing an 80-mesh, stainless-steel screen around the lamp. This reduced the transmission to 32.5% of the unscreened value and reduced the yield to 33 ± 3% of the value in control experiments. The quantum yield is apparently independent of light intensity.

The concentrations of maleic anhydride were large enough in all experiments to assure quantitative transfer of the triplet excitation of the sensitizers (see Quenching of Triplets above). Consequently dependence of the quantum yield on the concentration of maleic anhydride must be due to competition at some step other than energy transfer. Two likely candidates come to mind: (1) capture of intermediate in a thermal reaction and (2) a two-photon process. The latter possibility is ruled out by the linear response to a change in light intensity. The first possibility is the one that would have been anticipated on the basis of all suggested mechanisms.

The dependence of quantum yields on the concentration of maleic anhydride is attributed to competition between reactions 5 and 6, two thermal processes. The above mechanism, with the assumption that energy transfer (reaction 2) is quantitative, yields the following rate law

$$\Phi = \Phi_{ic} \frac{k_2 k_4 [\text{MA}]}{(k_2 + k_3)(k_4 [\text{MA}] + k_5)} \quad (7)$$

where  $\Phi_{ic}$  is the quantum yield for intersystem crossing by the sensitizer.

If the data in Table III are averaged and corrected for consumption of the reactant the numbers can be fitted surprisingly well to a function of the form of eq 7. The scatter of the numbers before averaging discourages us from a serious attempt to extract a value of the critical reactivity ratio,  $k_4/k_5$ , from the data although it must be on the order of ten.

The mechanism suggested predicts that the yields should fall off if the concentration of complex is reduced, at constant total maleic anhydride concentration, by dilution of the benzene with a cosolvent. The decrease should become significant when the concentration of the complex becomes small enough to allow radiationless decay of sensitizer triplets to compete with energy transfer. The data for experiments using dioxane, chloroform, and acetonitrile as cosolvents are

gathered in Table V. The data in the three series cannot be directly cross-compared because the light intensity was different in the three runs.

Table V. Effect of Dilution with Cosolvents<sup>a</sup>

[Benzene] <sub>0</sub> , M	Dioxane	Yield of product <sup>b</sup> Chloroform	Acetonitrile
1.1	0		
2.3		9.1 ± 0.4	15.0 ± 1.9

6.8		19.0 ± 0.5	65.9 ± 1.0
7.9	65.2 ± 4		82.7 ± 3.0
9.0		27.1 ± 1.0	94.3 ± 3.0
10.7	81.8	33.5 ± 1.5	98.9 ± 1.0

<sup>a</sup> [Benzophenone] = 0.10 M, [MA]<sub>0</sub> = 1.0 M. <sup>b</sup> Milligrams of product obtained from 3-ml samples irradiated as described in the Experimental Section for 7 hr.

The effect of variation of the concentration of benzene is surprising. If the value of Andrews and Keefer<sup>19</sup> for the dissociation constant is even close to correct, there should be enough of the complex in all solutions to effect complete quenching of benzophenone triplets. Consequently, there must be some reversible interaction with benzene *after* the energy-transfer step. The simplest way that we can see to include such a step is as follows

The excitation energies of the complex and monomeric maleic anhydride inferred from quenching studies (*vide supra*) would indicate that reaction 8 should be endothermic. The small decrease in quantum yield with increasing temperature reported by Angus and Bryce-Smith<sup>2</sup> may be due to change in the equilibrium constant for reaction 8. Another possibility is that the excited complex is stabilized by interaction with a second molecule of benzene to form a ternary triplet complex.

Formation of such a ternary complex might well be expected to effect unusual stabilization of the excited triplet. McGlynn and his co-workers<sup>25</sup> have pointed out that the excited singlet state of a complex should lie lower than the triplet if charge transfer is dominant in the excitation process. With two acceptor molecules in the complex, the triplet should be stabilized. It is even conceivable that the complex responsible for the quenching action is a 2:1 complex in the first place. Andrews and Keefer<sup>19</sup> found no evidence for such a species but their experiments were carried out with diluents and, as was previously mentioned, extrapolation of the spectroscopic properties of the complex as observed in chloroform solution to pure benzene is not very accurate.

**Attempts to Capture an Intermediate.** The proposed intermediate, 2, should be a reactive diene so (unsuccessful) attempts were made to intercept the species with dienophiles. Irradiation of a benzene solution containing 1.0 M maleic anhydride, 2.5 M methyl acrylate, and 0.10 M benzophenone gave only the usual adduct although a viscous yellow oil, probably a polymeric material, was also formed. A toluene solution containing 0.5 M maleic anhydride and 0.05 M benzophenone was irradiated for 15 hr at -77° with the hope that 2 would accumulate. The contents of the tubes were then added quickly to concentrated solutions of tetracyanoethylene. No adducts could be isolated.

**Quenching the Unsensitized Reaction.** Bryce-Smith and Lodge reported that the unsensitized reaction is not quenched by oxygen.<sup>5</sup> We irradiated samples sealed under oxygen at a pressure of 1 atm in parallel with degassed samples and found unmistakable evidence for quenching. The results are summarized in Table VI.

Table VI. Quenching of the Unsensitized Reaction by Oxygen

Series	[MA] <sub>0</sub> <sup>a</sup>	Percentage of reaction quenched <sup>b</sup>
1	2.00	23 ± 5
2	1.50	20 ± 7
3	0.20	31 ± 7

<sup>a</sup> Benzene solution. <sup>b</sup> Average results obtained from irradiation in parallel of five samples under oxygen and five degassed samples.

The effect is small but unmistakable. Other common quenchers, such as anthracene and azulene, were also tried but because of competitive absorption could not be used at concentrations greater than  $5 \times 10^{-4}$  M. Although some quenching was probably observed, the effect was not clearly outside the limits of experimental error. If the saturation solubility of oxygen in toluene is similar to that in benzene,<sup>26</sup> the oxygen concentration was about  $5 \times 10^{-3}$  M. Since quenching was observed, the rate constants for competitive reactions, including collapse to 2, must be of the order of  $5 \times 10^7$  moles l.<sup>-1</sup> sec.<sup>-1</sup>.

The experiment has considerable significance since it indicates that at least part of the unsensitized reaction goes by way of triplets. Since it is not feasible to do studies involving varying concentrations of a quencher, we cannot be sure that the triplet path is the only one.<sup>27</sup>

## Experimental Section

**Materials.** Acetonaphthone (Matheson Coleman and Bell, reagent grade) was recrystallized from acetic acid-water, mp 54.0°. Anthraquinone was recrystallized twice from acetic acid, mp 284–285°. Benzene (Matheson Coleman and Bell, Spectro quality) was generally used without purification. The material did not give a color on contact with sulfuric acid and less than 0.1% impurities was found by vapor chromatography. Benzaldehyde (Matheson Coleman and Bell, reagent grade) was distilled twice, the second

(26) M. Reznikovskii, Z. Tarasova, and B. Dogadkin, *Zh. Obshch. Khim.*, **20**, 63 (1950); *Chem. Abstr.*, **44**, 4754 (1950).

(27) NOTE ADDED IN PROOF. We now find that maleic anhydride is an efficient quencher of the fluorescence of triphenylene and naphthalene (see ref 1 for similar observations). Consequently the significance of inhibition by those compounds (Table I) should be reevaluated. This removes the apparent anomaly presented by the cases of triphenylene and *p*-cyanobenzophenone. An attempt to reproduce the spectrum shown in Figure 1, with a less sensitive instrument, gave no resolvable emission so we cannot be entirely certain that the original result was not due to the presence of an impurity.

time through a spinning-band column, bp 65° (25 mm). Benzil (Matheson Coleman and Bell, reagent grade) was recrystallized from ethanol-water and then from ligroin, mp 96.5–96.8°. Chloroform (Matheson Coleman and Bell, Spectro quality) was used without further purification. Chrysene, recrystallized and sublimed, was supplied by Dr. J. R. Fox. *p*-Cyanobenzophenone was obtained from Dr. C.-H. Wu; it was recrystallized from ligroin-benzene, mp 115.5–116°. *p*-Diacetylbenzene (Aldrich, research grade) had been chromatographed on alumina and then recrystallized twice by Dr. A. A. Lamola. 4,4'-Dichlorobenzophenone (K and K Laboratories) was used without further purification; its phosphorescence spectrum was taken by Dr. A. A. Lamola and showed no trace of benzophenone. Fluorenone (Matheson Coleman and Bell, reagent grade) was recrystallized once from ligroin and once from ethanol, mp 83.8–84.5°. Maleic anhydride (Matheson Coleman and Bell, reagent grade) was sublimed at 45° (0.5 mm) immediately before use. Naphthalene (Matheson Coleman and Bell) was recrystallized twice from ethanol. Propiophenone (Matheson Coleman and Bell, reagent grade) was recrystallized from ligroin at –5° and then distilled at 0.5 mm through a Vigreux column; the fraction boiling at 63–64° was collected for use. Tetracyanoethylene (Aldrich, research grade) was recrystallized from ethyl acetate-chloroform. Thioxanthone was treated with carbon black and then recrystallized twice from methanol, mp 209°. Toluene (Matheson Coleman and Bell reagent grade) was shaken three times with concentrated sulfuric acid, dried over calcium chloride, and distilled from sodium. Triphenylene (Aldrich, research grade) was sublimed, mp 194–198°. Xanthone (Aldrich) was passed through an alumina column, eluted with benzene, and then recrystallized twice from methanol.

**Procedures.** Most irradiations were carried out in the "merry-go-round," an apparatus in which a number of tubes are rotated

about a Hanovia immersion reactor containing a 450-w, medium-pressure lamp. The entire apparatus is placed in a constant-temperature water bath. The samples were placed in Pyrex culture tubes (13 mm o.d.) which had been constricted. The tubes were washed with Orvus soap, rinsed five times with distilled water and once with methanol, and dried at 125°. Solutions were prepared in volumetric flasks and 3- or 4-ml aliquots were added to the individual tubes. The samples were then degassed using three freeze-thaw cycles, with pumping at  $5 \times 10^{-4}$  mm, before being sealed off. The Pyrex tubes passed very little of the 2753- and 2804-Å lines from the source and in most experiments with sensitizers a uranium-glass filter having virtually no transmission below 3300 Å was used. No filter was used in experiments involving direct irradiation.

After irradiation the tubes were opened and the product was collected by suction filtration, washed with a few milliliters of cold reaction solvent, dried for 20 min at 115°, and weighed. The solubility of the adduct in all reaction solvents is too low for convenient measurement. However, varying amounts of product may have remained in the supernatant liquid by supersaturation, since crystal growth is very slow.

Some measurements of quantum yields were made using the collimated beam provided by the apparatus previously described.<sup>9</sup> Actinometry for runs with both systems was carried out by monitoring the reaction of benzophenone by benzhydrol.<sup>9</sup>

## Radical Additions of $\text{Cl-CCl}_3$ to *cis*-Cyclooctene<sup>1,2</sup>

James G. Traynham and Thomas M. Couvillon

Contribution from Coates Chemical Laboratories, Louisiana State University, Baton Rouge, Louisiana 70803. Received January 11, 1967

**Abstract:** Both photo- and thermally initiated additions of carbon tetrachloride to *cis*-cyclooctene give mainly stereoisomeric 1-chloro-4-(trichloromethyl)cyclooctanes, products of transannular addition. Small amounts of the stereoisomeric 1,2-addition products and several other minor products containing less chlorine per molecule are also formed. Peroxide-initiated addition of trichloromethanesulfonyl chloride (net addition of  $\text{Cl-CCl}_3$ ) produces the 1,2- and 1,4-addition products in the ratio 30:70. The activation energy requirement for transannular hydrogen atom shift in this system is estimated to be approximately 18 kcal/mole. Selective dehydrochlorinations of the addition products have been achieved; potassium hydroxide in alcoholic dimethyl sulfoxide produces mostly chloro-(dichloromethylene)cyclooctanes, but alcoholic silver nitrate leads to (trichloromethyl)cyclooctenes.

**T**ransannular hydride shifts during cationic reactions of medium-ring compounds were first reported in 1952<sup>3</sup> and are now considered to be characteristic of those compounds.<sup>4</sup> Although these rearrangements occur to small extents in unsubstituted cycloalkyl cations,

they become extensive when the initial carbonium ion center is flanked by an electron-withdrawing substituent.<sup>4</sup> Examples of transannular reactions involving radical intermediates have been far fewer in number than those involving cationic intermediates. Some<sup>5</sup> but not all<sup>6</sup> radical additions to 1,5-cyclooctadiene yield mostly substituted bicyclo[3.3.0]octanes as products (transannular C=C participation), and thiol addition to norbornadiene gives both normal and transannular products.<sup>7</sup> Recently, reports of transannular hydrogen abstraction by the intermediate alkoxy radical formed during decomposition of 1-methylcyclooctyl hypochlorite<sup>8</sup> and transannular hydrogen migration to a

carbon radical center during radical additions to medium-ring olefins<sup>9</sup> have been reported. Only the latter rearrangement is directly comparable to the hydride shifts characteristic of medium-ring carbonium ion chemistry, and when those reports<sup>9</sup> appeared, our own investigations of radical additions to the simple medium-ring olefin, *cis*-cyclooctene, were substantially complete.<sup>14</sup> We have described in detail the largely normal 1,2 addition of bromotrichloromethane to *cis*-cyclooctene.<sup>1c,10</sup> This paper describes our radical additions of Cl-CCl<sub>3</sub> (from carbon tetrachloride and from trichloromethanesulfonyl chloride) to *cis*-cyclooctene.<sup>1c</sup> These reactions are mainly transannular additions (product 4), and a rough estimate of the activation energy for transannular hydrogen atom shift in 2-(trichloromethyl)cyclooctyl radical (2) has been made.

Additions of carbon tetrachloride to 1 have been carried out in different ways: photo- and thermally initiated reactions in the absence of any solvent other than excess carbon tetrachloride, and photoinitiated reaction with benzene solvent. Although the addition of benzene to the reaction mixture led to a higher conversion of cyclooctene to products and to less polymer formation, the over-all results of the three kinds of additions were substantially the same. The principal products were isomeric C<sub>8</sub>H<sub>11</sub>Cl<sub>4</sub> compounds, formed in yields of 59–71%; several minor products containing 1–3 chlorines per 8–9 carbons were obtained in combined yields of about 24–15%. Some hexachloroethane was isolated in each of the addition experiments, confirming the radical nature of the reactions.

**Major Products.** In contrast to a patent claim that the thermal addition of carbon tetrachloride to cyclooctene gives 1,2-addition product 3,<sup>11</sup> our product mixtures from both kinds of additions consisted primarily of *cis*- and *trans*-1-chloro-4-trichloromethylcyclooctanes (4, X = Cl). This identity was established on the basis of nmr spectra, selective dehydrochlorinations, and conversion to 4-chlorocyclooctanone identical with an authentic sample.

The ratio of the areas of the nmr signals centered near –2.2 ppm (A) and –1.65 ppm (B)<sup>12</sup> is especially valuable for structure assignments in cycloalkane derivatives. The signals near –2.2 ppm (A) are associated with CH<sub>2</sub>CX (X = electron-withdrawing substituent

such as Cl or CCl<sub>3</sub>) or with CH<sub>2</sub>C=C, and those near –1.65 ppm (B) with more remote CH<sub>2</sub>. For a 1,2-disubstituted cyclooctane such as 3, the ratio A:B is 4:8;<sup>10</sup> for a 1,3 isomer, the ratio is 6:6, and for 1,4 and 1,5 isomers, it is 8:4.<sup>13</sup> The major fraction, C<sub>8</sub>H<sub>11</sub>Cl<sub>4</sub>, from each of the CCl<sub>4</sub> additions gave an A:B ratio of nearly 8:4, clearly excluding normal 1,2 addition. That fraction, separated from lower boiling reaction products by careful distillations, was further separated into solid and liquid isomers by low-temperature fractional crystallization from methanol. The nmr spectra of these isomers are similar, and each exhibits an A:B ratio of about 8:4. The infrared spectra of the isomers are nearly the same but differ sufficiently at 10–11 μ for quantitative analysis. By comparison of the infrared spectra of the original C<sub>8</sub>H<sub>11</sub>Cl<sub>4</sub> product mixtures and standard mixtures prepared from the separated isomers, the original mixtures were estimated to consist of about 30% solid and 70% liquid isomers.<sup>14</sup>

When either the liquid or the solid isomer, or a mixture of them, was dehydrochlorinated with 1 molar equiv of potassium hydroxide in a mixed solvent, the same olefin, identified by infrared and nmr spectra as a chloro(dichloromethylene)cyclooctane, was produced. This result clearly identifies the solid and liquid isomers as geometrical, not position, isomers. Further identification of the olefin product as 1-chloro-4-(dichloromethylene)cyclooctane (6) was accomplished by ozonolysis of it to 4-chlorocyclooctanone, an authentic sample of which was synthesized independently from 9-oxabicyclo[4.2.1]nonane (8). This identification is com-

pletely in accord with the nmr A:B ratio for the original

C<sub>8</sub>H<sub>11</sub>Cl<sub>4</sub> products and establishes that the radical addition of CCl<sub>4</sub> to cyclooctene proceeds mainly to give 5 (*cis* and *trans*).<sup>15</sup>

Bromotrichloromethane, on the other hand, adds equally exclusively to give *cis*- and *trans*-1-bromo-2-trichloromethylcyclooctane (3, X = Br).<sup>10</sup> Clearly the relative activation free energy requirements of the

Experimental Section for details. <sup>b</sup> Both *cis* and *trans* isomers were obtained. <sup>c</sup> Other unidentified products. These figures exclude polymer and undistillable material. <sup>d</sup> 5s = solid isomer, 5l = liquid isomer.

The reactions of intermediate 2-(trichloromethyl)-cyclooctyl radicals (2), steps 2 and 3, determine the course of the overall reaction. Abstraction of chlorine from tetrachloride requires more energy than abstraction of bromine from bromotrichloromethane. An allylic reagent with a radical chain transfer constant similar to those for Cl-CCl<sub>3</sub> and Br-CCl<sub>3</sub><sup>16</sup> would be expected to give more nearly equal amounts of products corresponding to 3 and 4.

Peroxide initiated addition of trichlorosulfonyl chloride<sup>16</sup> to 1 gave an 81% yield of 1,2-dichloro-1,2-dichloromethylcyclooctane product which was found by gas chromatography and nmr and infrared spectroscopic analyses to be 70% 5 (67% liquid and 33% solid isomers) and 30% 9. The nmr spectrum of the 1,2 isomer shows the expected A:B ratio of 4:8 and includes two signals for HCCl, separated by 18 cps and each

correspond to one H. These signals are virtually identical to those for the 1-bromo-2-trichloromethylcyclooctane (3, X = Br) obtained from BrCCl<sub>3</sub> addition;<sup>10</sup> in experiments with that product identified as a 1:1 mixture of *cis* and *trans* isomers.<sup>10</sup> Because of the correspondence of the spectra for 9 and 3 (X = Cl) we conclude that 9 is also a 1:1 mixture of geometrical isomers (which was not resolved by gas chromatography).

This unexpected composition is apparently completely independent of the reagent (BrCCl<sub>3</sub> or CCl<sub>4</sub>) involved in the product-forming step

Once the gas chromatography retention time and spectra for the 1,2-isomer mixture were at hand, careful reexamination of the data for the liquid 1,4 isomer from each CCl<sub>4</sub> addition revealed that it was contaminated by small amounts of 9 (2% from thermal addition, 5-7% from photoinitiated additions).

The yields of the major products (as well as the yields of the minor products described in the next section) obtained from the four additions to 1 are summarized in Table I.

In addition to the dehydrochlorination which established the geometrical isomerism of solid and liquid 5, other selective dehydrochlorinations were carried out with both 5 and 9. When dehydrochlorination is effected by alcoholic silver nitrate, a (trichloromethyl)cyclooctene is the major product formed from both 5 and 9, but with potassium hydroxide in mixed solvent a chloro(dichloromethylene)cyclooctane is the major one (different olefins from 5 and 9). When mixtures of 5 and 9 were used with limited amounts of dehydrochlorinating reagent, 9 was consumed the more rapidly

by potassium hydroxide, but 5 was consumed the more rapidly by silver nitrate. The differences in rates of reactions are apparently sufficiently large to offer promise for purification of one isomer at the expense of the other.

**Minor Products.** Several chlorine-containing products boiling lower than the C<sub>8</sub>H<sub>14</sub>Cl<sub>4</sub> isomers were obtained in very small amounts in each addition reaction. Although there were some differences among the four additions, the general picture for these minor products was consistent. These products were identified primarily by comparison of spectra and gas chromatography retention times with those of authentic samples (see Experimental Section for details). The product distribution data are summarized in Table I.

C. Walling, "Free Radicals in Solution," John Wiley and Sons, New York, N. Y., 1957, pp 95, 157. The chain-transfer constants for BrCCl<sub>3</sub> and CCl<sub>4</sub> are not accurately known but are apparently between 10 and 100 for BrCCl<sub>3</sub> and CCl<sub>4</sub>. (b) The relative ease of chain transfer by CCl<sub>4</sub>SO<sub>2</sub>Cl and CCl<sub>4</sub> is illustrated by the report that a 1:1 mixture of 5 and 9 is formed from CCl<sub>4</sub>SO<sub>2</sub>Cl and styrene, but only low molecular weight polymers are obtained with CCl<sub>4</sub> and styrene: E. C. L. Y. Kily, U. S. Patent 2,606,213 (Aug 5, 1962); *Chem. Abstr.*, 6440h (1962).

All of these products can be written as products of conventional radical reactions involving cyclooctene,  $\text{CCl}_4$ , and derived radical intermediates. The similarity of distribution among the four additions is not particularly helpful for considerations of mechanism details. Chlorocyclooctane is formed in significantly higher yield in the thermal addition than in the others, however, and this difference may stem from the fact that by-product  $\text{HCl}$  (which can add to 1) was trapped in the sealed apparatus used for thermal addition but was lost by continuous nitrogen sweep in the others.

The extent to which allylic hydrogen abstraction accompanies addition of  $\cdot\text{CCl}_3$  to cyclooctene is small (2–9% with  $\text{CCl}_4$ , 1% with  $\text{CCl}_3\text{SO}_2\text{Cl}$ ). By contrast, radical reaction of  $\text{CCl}_4$  with cyclohexene gives about equal amounts of addition and hydrogen abstraction.<sup>17</sup> Since the transition state for  $\cdot\text{CCl}_3$  addition presumably resembles reactants while that for hydrogen abstraction is more like products,<sup>18</sup> the low extent of hydrogen abstraction from cyclooctene may signal relatively poor allylic stabilization for 2-cyclooctenyl radical compared to 2-cyclohexenyl radical.<sup>19</sup>

In connection with identification of one of the minor products, chloroform was added under radical conditions (photoinitiation) to cyclooctene with low conversion. The expected product,<sup>20</sup> (trichloromethyl)cyclooctane, was formed in about 20% yield and accompanied by chlorocyclooctane (10%) and (dichloromethyl)cyclooctane (41%). The predominance of this last product in the mixture is unexpected on the basis of previous reports of chloroform additions to olefins,<sup>20</sup> and we plan to investigate such additions further.

**Energy Considerations.** The driving force for the transannular rearrangement of 2 is the destabilization of a radical center by neighboring trichloromethyl substituent. This destabilization, which is relieved by the rearrangement, is estimated to amount to more than 3.5–4.0 kcal/mole. A tertiary radical is more stable than a secondary one by about that amount,<sup>21</sup> and rearrangement of the tertiary 1-(2,2,2-trichloroethyl)cyclodecyl radical to a secondary one has been reported.<sup>22</sup>

The relative extents of transannular and vicinal radical addition depend on addend, temperature, and relative concentrations of cyclooctene and addend. The intermediate 2-substituted cyclooctyl radical is trapped effectively by good chain-transfer agents such as chlorine and bromotrichloromethane but not by carbon tetrachloride. The ratio of transannular 3 to vicinal 4 products was 17:1 for  $\text{CCl}_4$  addition and about 1:34 for  $\text{BrCCl}_3$  addition (addend:olefin molar ratio 4:1). These ratios lead to a calculated ratio of rate constants for bromine abstraction (from  $\text{BrCCl}_3$ ) and for chlorine abstraction (from  $\text{ClCCl}_3$ ) by 2-(trichloromethyl)cyclooctyl radical of 578:1, and the corresponding difference in free-energy change ( $\Delta\Delta G^\ddagger$ ) is 4.04 kcal/mole ( $T =$

317°K). The entropies of activation for the two processes should be quite similar except for the difference in symmetry numbers of  $\text{CCl}_4$  (12) and  $\text{BrCCl}_3$  (4), and  $\Delta E_a$  is calculated to be about 5.5 kcal/mole. This amount of energy, 5.5 kcal/mole, is about 29% of the difference in bond energies (19 kcal/mole<sup>21</sup>) of the  $\text{Cl-CCl}_3$  and  $\text{Br-CCl}_3$  bonds being broken in the two processes.<sup>22</sup> The well-known Hirschfelder rule predicts that the activation energies for a series of similar exothermic radical-abstraction reactions should be proportional to the bond-dissociation energy of the bond being broken.<sup>23</sup> If the proportionality is extended for reactions of 2-(trichloromethyl)cyclooctyl radical to include not only halogen abstraction from  $\text{X-CCl}_3$  but also (intramolecular) transannular hydrogen abstraction,  $\Delta E_a$  for hydrogen and chlorine abstractions is estimated to be about 5.8 kcal/mole ( $0.29 \times 20^{21b}$ ). Data for a good model of radical transfer involving 2 are not available, but activation energies for  $\text{Cl-CCl}_3$  abstractions by polystyrene and poly(methyl acrylate) radicals are 12.3 and 13.3 kcal/mole, respectively.<sup>16a</sup> Using these energies as an approximation of  $E_a$  for 2 reacting with  $\text{CCl}_4$ , we estimate that  $E_a$  for transannular hydrogen abstraction in this system is about 18–19 kcal/mole).<sup>24–27</sup>

Although the amount of 4 from  $\text{Cl-CCl}_3$  addition is small under any circumstances, the ratio of 4:3 is smaller at 150° (1:99) than at 44° (1:17), indicating that the transannular hydrogen migration does indeed have the higher activation energy.

## Experimental Section

Gas chromatographic analyses were obtained with a Barber-Colman Model 20 instrument equipped with a hydrogen flame detector and a 100-ft capillary column coated with SE-96 silicone. Preparative gas chromatography was performed with a Wilkens Aerograph Autoprep Model A-700 instrument equipped with a  $\frac{1}{8}$  in.  $\times$  20 ft silicone column. Nmr spectra were obtained with the assistance of Mr. R. Seab and Mr. W. Wegner on a Varian Associates HA-60 spectrometer, and all chemical shifts cited refer to tetramethylsilane as internal reference. Infrared spectra were obtained with Beckman IR-5 and IR-7 and Perkin-Elmer Models 21 and 137 instruments. Capillary melting points were obtained with a Thomas-Hoover apparatus and are uncorrected. Element microanalyses were performed by Mr. R. Seab in these laboratories.

(22) The activation energies for few chain-transfer reactions are accurately known.<sup>16a</sup>

(23) J. O. Hirschfelder, *J. Chem. Phys.*, **9**, 645 (1941).

(24) This estimate depends importantly on the proportions of products 3 and 4 from the additions of  $\text{Br-CCl}_3$  and  $\text{CCl}_4$ . The proportions we report were obtained in several experiments, and product ratios outside what we consider reasonable limits of experimental error do not drastically change the estimated activation energy for transannular hydrogen abstraction. For example, even if the ratio of 3:4 from  $\text{CCl}_4$  addition were actually 9:1 and that from  $\text{BrCCl}_3$  addition were actually 1:9, the same kind of calculation leads to an estimate of 17 kcal/mole for hydrogen abstraction.

(25) H. S. Johnson and C. Parr, *J. Am. Chem. Soc.*, **85**, 2544 (1963), have calculated that the potential activation energy for hydrogen transfer between  $\text{Me}_3\text{CH}_2$  and  $\text{Me}_2\text{CH}$  is 12 kcal/mole. This calculated energy however is slightly lower than the apparent activation energy for chlorine abstraction from  $\text{CCl}_4$  by polystyryl radical<sup>16a,22</sup> and would be inconsistent with the product distribution data from our experiments.

(26) The activation energy for transannular hydride transfer between oxygenated carbons ( $\text{O-C-H} \cdots \text{C=O}$ ) in the seven-membered ring of a dihydropoleadiene has very recently been estimated to be about 24 kcal/mole: private communication from Professor P. T. Lansbury, Sept. 1966. See P. T. Lansbury and F. D. Saeva, *J. Am. Chem. Soc.*, **89**, 1890 (1967).

(27) The activation energy ( $E_a$ ) for transannular hydrogen abstraction is higher than  $E_a$  for halogen abstraction from  $\text{XCCl}_3$  by the 2-(trichloromethyl)cyclooctyl radical, but because of the more favorable entropy of activation for the unimolecular (transannular) reaction, the free energy of activation ( $\Delta G^\ddagger$ ) for the hydrogen-abstraction process is in between those for the two bimolecular, halogen-abstraction reactions.

(19) Addition to cyclooctene is apparently favorable, however. In a preliminary study of relative rates by competitive reactions, cyclooctene was consumed by  $\cdot\text{CCl}_3$  1.8 times as rapidly as cyclohexene: unpublished experiments by D. B. Stone.

**Initiated Addition of  $\text{CCl}_4$ .** A solution of freshly distilled cyclooctene (75 g, 0.68 mole) in carbon tetrachloride (75 g, moles) was placed in a 500-ml quartz flask, deoxygenated with nitrogen stream for 10 min, suspended in a Rayonet photochemical reactor, and irradiated with 2537-Å light for a total of 40 hr. A nitrogen atmosphere was maintained over the reaction mixture during irradiation, and a cooling fan in the reactor kept the mixture at  $44^\circ$ . After 20 hr, irradiation was interrupted so that the flask which had become coated with a dark polymeric material, could be cleaned. The reaction mixture was returned to the flask, with nitrogen for 5 min, and irradiated for another 20 hr. The solution was concentrated on a rotary evaporator and then distilled at reduced pressure. Besides recovered cyclooctene (8 g), there were obtained 18.5 g of low-boiling products containing chlorine (fraction A) and 124 g (72%) of 1:1 addition product, bp  $97\text{--}116^\circ$  (0.2 mm) (fraction B).

*l.* Calcd for  $\text{C}_8\text{H}_{14}\text{Cl}_4$ : C, 40.95; H, 5.34. Found: C, 41.15; H, 5.75.

Portion of the distillate fraction B was dissolved in twice its volume of absolute methanol and chilled to  $-60^\circ$ . The solid which separated was collected and recrystallized three times from methanol ( $-10$  to  $-30^\circ$ ), mp  $64\text{--}65.5^\circ$ . It was subsequently isolated as 1-chloro-4-(trichloromethyl)cyclooctane, **5s**.

*l.* Calcd for  $\text{C}_8\text{H}_{14}\text{Cl}_4$ : C, 40.95; H, 5.34. Found: C, 41.17; H, 5.78.

The liquid remaining from the crystallizations was distilled at reduced pressure to give a liquid isomer of the solid product, bp  $90^\circ$  (2 mm).

*l.* Calcd for  $\text{C}_8\text{H}_{14}\text{Cl}_4$ : C, 40.95; H, 5.34. Found: C, 41.15; H, 5.58.

The proportions of solid and liquid  $\text{C}_8\text{H}_{14}\text{Cl}_4$  products isolated were 1:1 liquid:36% solid. The infrared spectra of both fractions exhibit strong absorptions for  $\text{CCl}_2$  ( $12.8\text{--}13.5\ \mu$ ) and absorptions for C—Cl ( $14.9\ \mu$  for solid,  $14.81\ \mu$  for liquid). They differ primarily in the relative intensities of peaks in the  $10\text{--}12\ \mu$  region. Two absorption peaks proved useful for quantitative analysis:  $10.2$  (liquid) and  $10.5\ \mu$  (solid). A plot of mole fraction of liquid isomer vs. the ratio of absorbance ( $A_{10.2}/A_{10.5}$ ) of standard mixtures prepared from the separated solid and liquid products was a smooth curve. The ratio of absorbance for the unseparated distillate B corresponded to 64% liquid and 36% solid products (**5l** and **5s**, respectively).

Gas chromatography indicated that the liquid product contained isomeric products, the major one (92%) being subsequently isolated as 1-chloro-4-(trichloromethyl)cyclooctane (**5l**) and the minor one (8%) as 1-chloro-2-(trichloromethyl)cyclooctane (**9**). Relative amounts of the three isomeric 1:1 addition products were 6% **5s**, 58.5% **5l**, and 5.5% **9**.

The reaction was carried out with a solution of *cis*-cyclooctene (0.25 mole), carbon tetrachloride (3.2 moles), and benzene (3.2 moles). Little dark polymer was formed, the irradiation was not stopped during 41 hr, and the conversion of cyclooctene to products was 93%. Product distribution nearly duplicated that obtained without benzene solvent. The yield of 1:1 addition product was 73%, and the distribution among the three isomers was 5% **5s**, 63% **5l**, and 7% **9**.

**Thermally Initiated Addition of  $\text{CCl}_4$ .** A mixture of *cis*-cyclooctene (61 g, 0.55 mole) and carbon tetrachloride (470 g, 3.1 moles) was placed in a Parr medium-pressure apparatus at  $155^\circ$  for 4.5 hr at 1000 psi. The mixture was concentrated on a rotary evaporator and distilled at reduced pressure. After a low-boiling fraction [15.1 g,  $30\text{--}108^\circ$  (1.4 mm)] had been collected, the major product, consisting of isomeric  $\text{C}_8\text{H}_{14}\text{Cl}_4$  compounds, was obtained; 16%, bp  $108\text{--}130^\circ$  (1.4 mm). Infrared analysis (see above) of the fraction indicated that it consisted of 67% liquid and 33% solid products, which were subsequently separated by crystallization from methanol. The solid obtained was identical with that obtained from the photochemical experiments (mp  $64\text{--}65.5^\circ$ ; infrared melting point showed no depression). A gas chromatogram of the liquid portion indicated the presence of a small amount of isomer **2**. The distribution of the three isomeric 1:1 addition products was 33% **5s**, 65% **5l**, and 2% **9**.

**Purification of 1:1 Addition Products.** Nmr Spectra. The nmr spectrum of the liquid portion of the major product from the addition reactions consisted of multiplets centered near  $-4.23$  ppm equivalent to one proton,  $\text{HCCl}$ ,  $-2.6$  ppm (1 H,  $\text{HCCCl}_2$ ), 7.5 ppm (7.5 H,  $\text{CH}_2\text{CCl}$  and  $\text{CH}_2\text{CCl}_2$ ), and  $-1.65$  ppm (4.5 H,  $\text{CH}_2\text{CH}_2$ ).<sup>28</sup> The nmr spectrum of the solid isomer isolated

consisted of multiplets centered near  $-4.20$  ppm (1 H,  $\text{HCCl}$ ),  $-2.75$  (1 H,  $\text{HCCCl}_2$ ),  $-2.2$  ppm (8 H,  $\text{CH}_2\text{CCl}$  and  $\text{CH}_2\text{CCl}_2$ ), and  $-1.65$  ppm (4 H,  $\text{CH}_2\text{CH}_2\text{CH}_2$ ). These spectra exclude 1,2-addition products **9**, which would give a signal at  $-1.65$  ppm equivalent to 8 H, and one at about  $-2.2$  ppm, equivalent to 4 H, exactly opposite to those obtained here. The fractional equivalence of these two signals for the liquid fraction is consistent with the gas chromatographic analysis, indicating contamination by a small amount of the 1,2 isomer.

**Dehydrochlorination with KOH.** A solution of the mixed 1:1 addition product (50 g, 0.19 mole) in DMSO (120 ml), methanol (35 ml), and water (5 ml) was added to a solution of potassium hydroxide (0.20 mole), water (10 ml), methanol (25 ml), and DMSO (25 ml). The mixture was stirred at  $28^\circ$  for 5 hr, methanol (50 ml) was added to obtain a homogeneous solution, and the solution was stirred for 3 hr more. It was poured into 300 ml of water and extracted with four 150-ml portions of petroleum ether. The combined organic material was washed thoroughly with water and concentrated by rotary evaporation. Gas chromatography indicated that some  $\text{C}_8\text{H}_{14}\text{Cl}_4$  remained, but nearly all (about 82%) had been converted to a single olefinic product with detectable amounts of other products. Distillation gave a center cut at bp  $121\text{--}123^\circ$  (3.5 mm).

*Anal.* Calcd for  $\text{C}_8\text{H}_{12}\text{Cl}_2$ : C, 47.50; H, 5.76. Found: C, 47.53; H, 5.73.

The infrared and nmr spectra of the product were devoid of absorptions for olefinic hydrogens. The infrared spectrum did include intense absorptions for  $\text{C}=\text{CCl}_2$  ( $6.23$  and  $11.1\ \mu$ ) but none for  $\text{CCl}_2$ . The nmr spectrum included a quintet ( $J = 5.5$  cps) at  $-4.1$  ppm (1 H,  $\text{HCCl}$ ) whose resolution was better at  $60^\circ$  than at room temperature. These data indicate that the dehydrochlorination product is a chloro(dichloromethylene)cyclooctane. The same product was obtained in approximately equal yields from equivalent but smaller scale dehydrochlorinations of the separated solid and liquid fractions.<sup>29</sup>

**Ozonolysis of **6**.** Ozone (52 mmoles, about 5% in a stream of oxygen from a Welsbach T-23 ozonator) was passed during 5 hr into an ice-chilled  $\text{CCl}_4$  solution of the chloro(dichloromethylene)cyclooctane (**6**, 10.0 g, 44 mmoles). The saturated solution was then allowed to stand for several hours at  $0^\circ$  before the solvent was removed on a rotary evaporator (temperature kept below  $45^\circ$ ). The gummy residue was dissolved in 100 ml of acetic acid and reduced by the gradual addition at room temperature of powdered zinc (6.5 g) with vigorous stirring. The mixture was diluted with 200 ml of water and extracted three times with petroleum ether. The combined organic material was washed with water and sodium bicarbonate solution, dried, and concentrated. Gas chromatographic analysis indicated some starting olefin (varying amounts up to 30% in different experiments) together with the ozonolysis products. (In some experiments, the reaction mixture was separated by reduced pressure distillation; in others, it was examined directly by infrared spectroscopy and derivatization.) The ozonolysis mixture consisted of a minor product, a cyclooctenone (not conjugated,  $\lambda_{\text{max}}$   $1705\ \text{cm}^{-1}$ ), and a chlorocyclooctanone, the major product. The chlorocyclooctanone exhibited intense infrared absorption at  $1706\ \text{cm}^{-1}$ , clearly excluding 2-chlorocyclooctanone ( $\text{C}=\text{O}$  at  $1714$  and  $1725\ \text{cm}^{-1}$ ).<sup>30</sup> The 2,4-dinitrophenylhydrazone was recrystallized three times from 95% ethyl alcohol, mp  $150\text{--}152^\circ$ . The infrared spectrum and melting point of this derivative were identical with those of the 2,4-dinitrophenylhydrazone of authentic 4-chlorocyclooctanone (synthesis described below).

*Anal.* Calcd for  $\text{C}_{14}\text{H}_{17}\text{N}_4\text{O}_6\text{Cl}$ : C, 49.34; H, 5.03. Found: C, 49.42; H, 5.54.

**Independent Synthesis of 4-Chlorocyclooctanone (**7**).** Addition of a small amount of zinc chloride (about 0.5 g) to a mixture of 9-oxabicyclo[4.2.1]nonane (**8**)<sup>31,32</sup> (2.6 g, 18 mmoles) and acetyl

(29) Dehydrochlorinations with potassium hydroxide in aqueous ethanol or methanol were slow and gave complex mixtures of products. Potassium *t*-butoxide in DMSO gave a rapid, exothermic reaction which also led to a complex mixture of products. These product mixtures, which were unhelpful for structure identification, contained about 15–20% of the chloro(dichloromethylene)cyclooctane.

(31) Prepared by the oxidation of cyclooctanol with lead tetraacetate: (a) R. M. Moriarty and H. C. Walsh, *Tetrahedron Letters*, 465 (1965); (b) A. C. Cope, M. Gordon, S. Moon, and C. H. Park, *J. Am. Chem. Soc.*, 87, 3119 (1965).

Cyclooctane gives a single nmr signal at  $-1.65$  ppm.

chloride (15 g) initiated a vigorous reaction<sup>34</sup> which was moderated by cooling the reaction flask in a water bath. After the initial reaction had subsided, the mixture was refluxed for 20 min. Gas chromatographic analysis indicated that no 8 remained in the mixture.<sup>35</sup> The mixture was diluted with petroleum ether, and the excess acetyl chloride was hydrolyzed with ice. Conventional separation and work-up gave a low-boiling fraction (about 1 g) whose infrared spectrum was characteristic for cyclooctenyl acetate and another fraction [2.5 g, bp 85–115° (2 mm)] whose spectrum was consistent with 4-chlorocyclooctyl acetate ( $\lambda_{\text{max}}$  5.78, 8.1, and 14.9  $\mu$ ). This chloro acetate (2.5 g, 12 mmoles) was reduced in ethyl ether solution with lithium aluminum hydride (0.35 g, 9 mmoles). Conventional work-up (acidic hydrolysis) and removal of solvent left crude 4-chlorocyclooctanol which was dissolved in acetone (25 ml) and oxidized directly at 0° with a chromic acid solution (1.5 g, 15 mmoles, of  $\text{CrO}_3$  in 9 ml of 30%  $\text{H}_2\text{SO}_4$ ). After the mixture was diluted with water and extracted with petroleum ether, the organic solution was washed thoroughly with water, dried with calcium chloride, and concentrated. Gas chromatographic analysis indicated that the principal constituent of the residual liquid had a retention time identical with that of the ketone obtained from the ozonolysis of 6. The infrared spectrum ( $\lambda_{\text{max}}$  1706  $\text{cm}^{-1}$ ), nmr spectrum (quintet at  $-4.15$  ppm), and 2,4-dinitrophenylhydrazone derivative (mp 149–151.5°, the mixture melting point showed no depression) of this sample of 4-chlorocyclooctanone also matched the corresponding data for the ozonolysis product.

**Reaction of Trichloromethanesulfonyl Chloride with Cyclooctene.** During 1.5 hr, a solution of *cis*-cyclooctene (38 g, 0.35 mole) and benzoyl peroxide (8 g, 0.04 mole) in benzene (150 ml) was added to a refluxing solution of trichloromethanesulfonyl chloride (100 g, 0.45 mole, Eastman Practical Grade) in benzene (150 ml). Titration of evolved  $\text{SO}_2$  with iodine indicated that 38% of the sulfonyl chloride had decomposed in 30 min after addition was complete. The mixture was refluxed for 15 hr to ensure complete decomposition of the peroxide. A gas chromatogram of the reaction mixture before distillation showed two principal products (85%) of relative area 30:70 and at least 18 minor components. Distillation at reduced pressure gave a small amount of low-boiling material and 75 g (81%) of mixed  $\text{C}_8\text{H}_{14}\text{Cl}_4$  products, bp 90–114° (0.5 mm). The conversion of cyclooctene was greater than 96%. The mixture of products was analyzed by gas chromatography and infrared and nmr spectroscopy. The product distribution data are summarized in Table I.

The 1,2 and 1,4 isomers of  $\text{C}_8\text{H}_{14}\text{Cl}_4$  (5 and 9) are resolved by gas chromatography (140°, 100-ft SE-96 silicone capillary column). The nmr spectrum of the  $\text{C}_8\text{H}_{14}\text{Cl}_4$  mixture was used to confirm the gas chromatographic analysis. The integrated absorption centered at  $-4.75$  ppm ( $\text{HCCl}$ , 1,2 isomer) was compared with that at  $-4.25$  ppm ( $\text{HCCl}$ , 1,4 isomer), and the relative intensities of the absorptions to the left and right of  $-1.83$  ppm were estimated (a 5:8 ratio is expected for the pure 1,2 isomer, a 9:4 ratio for the 1,4 isomer). The three analyses gave concordant results: 31% 1,2 isomer and 69% 1,4 isomer.

The infrared spectrum of the highest boiling  $\text{C}_8\text{H}_{14}\text{Cl}_4$  fraction indicated that both the liquid and solid 1,4 isomers were present. The solid isomer was separated by fractional crystallizations, mp and mmp 64.5–65°. The liquid 1,4 and 1,2 isomers could not be separated cleanly by distillation, but repeated distillations through a 12-in. packed column gave fractions enriched in 1,2 isomer (77% purity) and 1,4 isomer (86% purity). The identity of the liquid 1,4 isomer was confirmed by comparison of its nmr and infrared spectra with those of previously identified samples ( $\text{CCl}_4$  additions above). The nmr spectrum of the 1,2 isomer is almost identical with that of 1-bromo-2-(trichloromethyl)cyclooctane (1:1 *cis-trans* mixture);<sup>10</sup> it includes a pair of triplet-like signals ( $J = 5.5$  cps) centered at  $-4.90$  ppm ( $\text{HCCl}$ , *cis* isomer) and  $-4.60$  ppm ( $\text{HCCl}$ , *trans* isomer). The ratio of signal intensity at  $-2.2$  ppm to that

at  $-1.65$  ppm was 5:8 (after correction for 23% 1,4 isomer). The infrared spectrum of the 1,2 isomer was similar to the spectra of the two 1,4 isomers in the 7–11- $\mu$  region; the C–Cl absorption frequency was recorded at 690  $\text{cm}^{-1}$  compared to 675 and 672  $\text{cm}^{-1}$  for the liquid and solid 1,4 isomers, respectively.

**Minor Products from Addition Reactions.** The lower boiling fraction from the distillations of the addition reaction mixture were fractionally distilled at reduced pressure and analyzed primarily by gas chromatography. Few of the components responsible for the 11–14 gas chromatography peaks were isolated in sufficient quantity for complete identification, but seven have been rather firmly identified by comparisons of gas chromatographic retention times and infrared spectra with those of authentic samples. These minor products are described in order of increasing gas chromatography retention times; the estimated yields for the several addition reactions are summarized in Table I.

Hexachloroethane was identified by sublimation temperature (184°) and infrared spectrum.<sup>36</sup>

3-Chloro-1-cyclooctene had the same retention time as authentic chloride prepared from 2-cycloocten-1-ol and thionyl chloride. The distillate fraction rich in this component gave an immediate precipitate with cold alcoholic silver nitrate.

Chlorocyclooctane showed the same retention time as an authentic sample prepared by the addition of HCl to cyclooctene.

*trans*-1,2-Dichlorocyclooctane showed the same retention time as an authentic sample prepared by the addition of chlorine to cyclooctene.<sup>37,38</sup>

Dichloromethylenecyclooctane was separated in about 91% purity by preparative gas chromatography; the infrared spectrum included only trace absorptions for  $\text{C}=\text{CH}$  and intense ones for  $\text{C}=\text{CCl}_2$  (6.21 and 11.1  $\mu$ ).

*Anal.* Calcd for  $\text{C}_8\text{H}_{12}\text{Cl}_2$ : C, 56.0; H, 7.3. Found: C, 55.3; H, 7.4.

A (trichloromethyl)cyclooctene was separated in low purity by preparative gas chromatography; the infrared spectrum included absorptions for  $\text{C}=\text{CH}$  (3.3 and 6.03  $\mu$ ) and  $\text{CCl}_3$  (13  $\mu$ , intense). The gas chromatographic retention time and infrared spectrum of this product were different from those of the 4-(trichloromethyl)-1-cyclooctene obtained by  $\text{AgNO}_3$  dehydrochlorination of 5.

(Trichloromethyl)cyclooctane was obtained in about 91% purity by preparative gas chromatography; the infrared spectrum included no absorptions for  $\text{C}=\text{CH}$  but an intense one at 13  $\mu$  for  $\text{CCl}_3$ . The nmr spectrum consisted of multiplets centered at  $-2.6$  (1 H,  $\text{HCCCl}_3$ ),  $-2.2$  (4 H,  $\text{CH}_2\text{CCCl}_3$ ), and  $-1.6$  ppm (8 H,  $\text{CH}_2\text{CH}_2\text{CH}_2$ ). Data for this product correspond to those of an authentic sample of (trichloromethyl)cyclooctane, prepared from chloroform and cyclooctene.

**Dehydrohalogenation of 5 with  $\text{AgNO}_3$ .** A mixture of 5s (9.04 g, 34.2 mmoles), silver nitrate (6.00 g, 35 mmoles), and aqueous methanol (50 ml, 90 vol. %  $\text{MeOH}$ ) was stirred at 45° for 4 hr, filtered from precipitated silver chloride, and diluted with ethyl ether. The ether solution was washed thoroughly with water, dried, and distilled. In addition to recovered starting material [4.0 g, 44%, bp 105–107° (0.2 mm)], a dehydrochlorination product was obtained in 93% yield (based on 5s consumed), bp 74–80° (0.15–0.2 mm).

*Anal.* Calcd for  $\text{C}_8\text{H}_{12}\text{Cl}_2$ : C, 47.50; H, 5.76. Found: C, 47.40; H, 5.93.

The infrared spectrum of this product included absorptions for  $\text{C}=\text{CH}$  (3.30  $\mu$ ),  $\text{C}=\text{C}$  (6.02  $\mu$ ), and  $\text{CCl}_3$  (12.8–13.6  $\mu$ , intense). The nmr spectrum included multiplet signals centered at  $-5.7$  (2 H,  $\text{C}=\text{CH}$  with splitting virtually identical with the signal for *cis*-cyclooctene),<sup>39</sup>  $-2.6$  (1 H,  $\text{HCCCl}_3$ ),  $-2.2$  (6 H,  $\text{CH}_2\text{CCCl}_3$  and  $\text{CH}_2\text{C}=\text{C}$ ), and  $-1.6$  ppm (4 H,  $\text{CH}_2\text{CH}_2\text{CH}_2$ ). The ratio of the signals at  $-5.7$ ,  $-2.2$ , and  $-1.6$  ppm is consistent only with 4-(trichloromethyl)-1-cyclooctene among the four isomeric (trichloromethyl)cyclooctenes. The precision of the integrated areas is such that a small contamination (<4%) by 5-(trichloromethyl)-1-cyclooctene would not be detected.

Similar treatment of 5l with silver nitrate gave a 50% conversion to product whose infrared spectrum and gas chromatographic

(32) The infrared spectrum of our product was identical with the published spectrum for 9-oxabicyclo[4.2.1]nonane<sup>33</sup> and gave no indication of contamination by the [3.3.1] isomer.

(33) A. C. Cope and B. C. Anderson, *J. Am. Chem. Soc.*, **79**, 3892 (1957).

(34) A. C. Cope and A. Fournier, *ibid.*, **79**, 3896 (1957), describe the comparable reaction between the oxide and acetyl bromide. We find that the reaction with the less-reactive acetyl chloride is facilitated by zinc chloride catalyst.

(35) In a previous experiment without zinc chloride, the 9-oxabicyclo[4.2.1]nonane was not consumed after 24-hr reflux with excess acetyl chloride.

(37) E. A. Forbes, B. R. Gofton, R. P. Houghton, and E. S. Waigh, *J. Chem. Soc.*, 4711 (1957).

(38) P. W. Havinga, *Rec. Trav. Chim.*, **81**, 1053 (1962). This reference includes the infrared spectrum, which is identical with that of our authentic sample.

(39) G. V. Smith and H. Kriloff, *J. Am. Chem. Soc.*, **85**, 2016 (1963).

retention time were identical with those of the 4-(trichloromethyl)-1-cyclooctene obtained from 5s. The conversion of  $C_8H_{14}Cl_4$  to dehydrochlorination product by silver nitrate solution was not increased substantially by prolonged heating.

**Dehydrohalogenations of Mixed 1,2 and 1,4 Isomers of  $C_8H_{14}Cl_4$ .**  
**A. KOH in Mixed Solvent.** A mixture prepared by adding a solution of potassium hydroxide (1.1 g, 21 mmoles) in 18 ml of solvent (DMSO-MeOH- $H_2O$ , 10:5:3) to a solution of  $C_8H_{14}Cl_4$  (4.4 g, 16.7 mmoles, 65% 1,2 isomers, 35% 1,4 isomers) in 5 ml of methanol and 35 ml of DMSO was stirred at room temperature for 6 hr. It was diluted with water and worked up as was the previous basic dehydrochlorination. After removal of solvent, the product mixture (3 g) was shown by gas chromatography to consist of five components (relative peak areas 9:5:54:18:13). The last two peaks corresponded in retention times to 1-chloro-4-(dichloromethylene)cyclooctane and 1-chloro-4-(trichloromethyl)cyclooctane, respectively. A peak corresponding to the starting 1,2 isomers was completely absent.

The major component (area 54) had a retention time indicative of 3 chlorine atoms per molecule.<sup>40</sup> The infrared spectrum of the product mixture showed only trace absorption for olefinic hydrogen, intense absorptions for  $C=CCl_2$  at 6.23 and 11.02  $\mu$ , and weak absorption for  $CCl_3$ . Since 6 absorbs at 11.10  $\mu$ , the absorption at 11.02  $\mu$  can be attributed to the major component of the product mixture. This product is tentatively identified as 1-chloro-2-(dichloromethylene)cyclooctane. On the basis of retention time, the first product is tentatively identified as a (dichloromethylene)-cyclooctene. The 1,2 isomers of  $C_8H_{14}Cl_4$  apparently undergo dehydrochlorination more rapidly under these conditions than do the 1,4 isomers.

**B. Alcoholic  $AgNO_3$ .** A mixture of  $C_8H_{14}Cl_4$  (3.6 g, 13.6 mmoles, 65% 1,2 isomers, 35% 1,4 isomers) and silver nitrate (2.47 g, 16.6 mmoles) in aqueous methanol (50 ml, 90 vol. % MeOH) was refluxed for 5 hr, filtered, and diluted with water. Work-up as previously described gave 3 g of a product mixture shown by gas chromatographic analysis to consist of four components (relative peak areas 25:5:60:10). The last two peaks corresponded in retention times to the 1,2 and 1,4 isomers of  $C_8H_{14}Cl_4$ , respectively, and the first peak to 4-(trichloromethyl)-1-cyclooctene. On the

basis only of retention time and product expected from 4, the intermediate peak is tentatively associated with 3-(trichloromethyl)-1-cyclooctene. The 1,4 isomers undergo dehydrochlorination about six times more rapidly under these conditions than do the 1,2 isomers.

**Photoinitiated Addition of Chloroform to Cyclooctene.** A mixture of freshly distilled *cis*-cyclooctene (42 g, 0.38 mole) and chloroform (360 g, 3.0 moles) was placed in a quartz tube, deoxygenated with a stream of nitrogen for 15 min, and irradiated with 2537-A light for 65 hr. A slow stream of nitrogen swept over the mixture during the irradiation and into a trap containing a 10% aqueous sodium hydroxide solution. Distillation of the irradiated mixture gave recovered chloroform, cyclooctene (35 g, 83%), and a higher boiling product mixture (8 g) shown by gas chromatography to consist of three components. The most volatile of the three was separated by distillation [bp 40–42° (0.6 mm)] and identified as chlorocyclooctane by comparison with an authentic sample. Its nmr spectrum consisted of a well-resolved quintet ( $J = 5.0$  cps) centered at  $-4.14$  ppm (1 H,  $HCCl$ ) and multiplets centered at  $-2.02$  ppm (4 H,  $CH_2CCl$ ), and  $-1.65$  ppm (6 H,  $CH_2CH_2CH_2$ ). The other higher boiling components were separated by preparative gas chromatography. The major one gave an analysis for  $C_8H_{14}Cl_2$ ; its infrared spectrum showed absorption at 13.4  $\mu$  and none for  $C=C$ ; its nmr spectrum consisted of a sharp doublet ( $J = 3.0$  cps) at  $-5.07$  ppm (1 H,  $CHCHCl_2$ ) and multiplets at  $-2.1$  ppm (1 H,  $CHCHCl_2$ ) and  $-1.65$  ppm (14 H,  $CH_2$ ). This product is identified as (dichloromethyl)cyclooctane.

*Anal.* Calcd for  $C_8H_{14}Cl_2$ : C, 55.41; H, 8.25. Found: C, 55.77; H, 8.29.

The third product was identified by its analysis for  $C_8H_{14}Cl_3$ , its infrared spectrum (intense absorption at 13  $\mu$ ), and its nmr spectrum (see above) as (trichloromethyl)cyclooctane.

The approximate yields of these three products, based on cyclooctene consumed, were 10% chlorocyclooctane, 41% (dichloromethyl)cyclooctane, and 20% (trichloromethyl)cyclooctane. Traces of hexachloroethane, *trans*-1,2-dichlorocyclooctane, and dichloromethylenecyclooctane were detected by gas chromatography. Treatment of the alkaline trap solution with acetic acid and silver nitrate gave silver chloride in molar amount, equivalent to the sum of the three major products.

**Acknowledgment.** The authors are grateful for helpful discussions with Professor W. A. Pryor during the preparation of the manuscript.

(40) Ranges of retention times for cyclooctane derivatives containing one, two, and three chlorines per molecule ( $C_8$  or  $C_9$ ), respectively, were separated by several minutes in our gas chromatographic analyses.

# Wagner–Meerwein Rearrangements in the Solvolyses of Benzobicyclo[2.2.2]octenyl and -octadienyl Brosylates and Nuclear Magnetic Resonance Spectra of the Benzobicyclo[3.2.1]octadiene and Benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octene Systems

Contribution from Shionogi Research Laboratory, Shionogi and Company, Ltd., Fukushima-ku, Osaka, Japan. Received January 20, 1967

**Abstract:** Rate constants and products in the acetolyses of *endo*- and *exo*-benzobicyclo[2.2.2]octen-2-yl (I-OBs and II-OBs) and -octa-5,7-dien-2-yl brosylates (III-OBs and IV-OBs) were determined. The rates of I-OBs, II-OBs, III-OBs, and IV-OBs at 25° relative to that of bicyclo[2.2.2]octan-2-yl brosylate were 0.92, 2.6, 11, and 2.9, respectively. The reaction with I-OBs proceeds with complete rearrangement forming quantitatively a mixture of axial and equatorial benzo[3,4]bicyclo[3.2.1]octen-2-ol acetates. The product from II-OBs is an 83:17 mixture of benzo-bicyclo[2.2.2]octen-2-ol acetate and rearranged benzo[6,7]bicyclo[3.2.1]octen-2(axial)-ol acetate. Only in this case is the reaction stereospecific. In the acetolysis of III-OBs, the major products are axial and equatorial benzo-[3,4]bicyclo[3.2.1]octa-3,6-dien-2-ol acetates, and the minor products are *exo*- and *endo*-benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octen-6-ol acetates. The acetolysis of IV-OBs yields a mixture of axial and equatorial benzo[6,7]bicyclo[3.2.1]octa-3,6-dien-2-ol acetates with complete rearrangement. The nmr spectra of the newly formed benzobicyclo[3.2.1]octadienyl and benzotricyclo[3.2.1.0<sup>2,7</sup>]octenyl derivatives were examined for structural elucidation. Several long-range spin couplings found in these systems are described.

The chemistry of bridged benzocyclenes is one of the research interests in our laboratory. Synthesis of the smallest bridged benzocyclene ever known, benzo-bicyclo[2.1.1]hexene, was recently achieved.<sup>1</sup> Some reported parts of our studies of carbonium ion reactions in the benzonorbornenyl system demonstrated the advantage of discussing the participation effect and the structure of the transition state involved in reactions of this kind.<sup>2</sup> Along this line, this paper reports a comprehensive study of the rates and Wagner–Meerwein rearrangements in the acetolyses of benzobicyclo[2.2.2]octen-2-yl and -octa-5,7-dien-2-yl brosylates. Rearrangements in the dienyl derivatives produced compounds having new bridged unsaturated systems. The structure elucidation of these compounds leaned heavily on their nmr spectra, and the proton spin-decoupling experiments (nmr and nmtr spectroscopy) performed here are considered to be a model technique for the structure determination of molecules of these kinds.

I and II

III and IV

**Preparations.** Syntheses and properties of *endo*- and *exo*-benzobicyclo[2.2.2]octen-2-ols (I-OH and II-OH) used in this study are already known.<sup>3-5</sup> Lithium aluminum hydride reduction of benzobicyclo[2.2.2]octa-5,7-dien-2-one<sup>3</sup> led to a mixture of the *endo*-

and *exo*-dienols, III-OH and IV-OH, each of which was isolated in the pure state by elution chromatography. The brosylates of these four alcohols were prepared by standard procedures. The brosylates, III-OBs and IV-OBs, were rather unstable and could be stored for a few days in a dry ether solution at 0°.

**Solvolysis Rates.** The rates of acetolyses were carried out in glacial acetic acid containing equivalent sodium acetate by the standard procedure.<sup>2b,6</sup> In each experiment the reaction was followed to at least 80% completion. Good first-order kinetics were observed in the reactions of all the brosylates, and the infinity titers corresponded to theory. The solvolysis rates are summarized in Table I, together with the derived activation parameters and the data of relevant compounds. For comparison, the rate constants at 25.0° were calculated from Arrhenius plots. The relative rates are determined taking that of the parent bicyclo[2.2.2]octyl brosylate (V-OBs) as unity. Table I also lists, for discussion, the *exo:endo* rate ratios in the bicyclo[2.2.2]octenyl, benzobicyclo[2.2.2]octenyl, and benzobicyclo[2.2.2]octadienyl series.

Ethanolyses of I-OBs and II-OBs also followed good first-order kinetics and the rate constants are presented in footnotes to Table I.

**Solvolysis Products.** For product determination, the acetolyses were carried out under the same conditions used for the rate studies. In all cases, the brosylates quantitatively produced mixtures of acetates. The product composition was examined by vpc analysis of the acetate mixtures and, in addition, of the alcohol mixtures derived therefrom by lithium aluminum hydride reduction. Each component of the acetate mixtures was isolated by preparative vpc. The yields of products were determined by vpc with the isolated pure

<sup>a</sup> The present runs were conducted in glacial acetic acid containing equivalent sodium acetate. <sup>b</sup> Controlled to 0.02° in the present work. In ethanolysis,  $k_1$  at 35.02° was  $6.40 \times 10^{-5}$  sec<sup>-1</sup>. <sup>c</sup> In ethanolysis,  $k_1$  at 35.02° was  $3.44 \times 10^{-5}$  sec<sup>-1</sup>. Thus the *exo:endo* ratio was 5.4. Reference 19a. <sup>d</sup> For the tosylate, Goering and Sloan<sup>20b</sup> reported the values of  $6.8 \times 10^{-5}$  sec<sup>-1</sup> at 30.07° and  $7.4 \times 10^{-5}$  at 49.03°. Extrapolation gave  $k_1$  (25°) =  $3.41 \times 10^{-5}$ ,  $\Delta H^\ddagger$  = 23.9 kcal, and  $\Delta S^\ddagger$  = -3.9 cal/deg. <sup>e</sup> Reference 21. <sup>f</sup> The rates of tosylate were reported  $6.1 \times 10^{-5}$  sec<sup>-1</sup> at 25.0 (see ref 21) and  $2.4 \times 10^{-5}$  sec<sup>-1</sup> at 18.2° in ref 22. <sup>g</sup> Extrapolated from the data for other temperatures taken from H. C. Brown and G. Ham, *J. Am. Chem. Soc.*, **78**, 2735 (1956). <sup>h</sup> S. Winstein, *et al.*, *ibid.*, **74**, 1127 (1952), reported the values of  $1.71 \times 10^{-7}$  sec<sup>-1</sup> at 25.0°,  $\Delta H^\ddagger$  = 26.6 kcal, and  $\Delta S^\ddagger$  = -0.3 cal/deg. <sup>i</sup> The observed value in footnote i. <sup>j</sup> Data of the tosylate cited from ref 2b. <sup>k</sup> Calculated from the rate of tosylate with ROBS/ROTs = 3.

etates and a proper compound being used as an internal reference. The estimated error in the yields is ±2%. For discussion, it was considered important to check, in all the acetolyses, the products of retention of configuration and those of inversion. These experiments were also performed by vpc. Demonstration of the absence of such a compound means that it was not formed in amounts greater than 0.5% yield. The product mixtures contained derivatives of benzyl acetate and cyclopropylcarbinyl acetate. They are anticipated to undergo acid-catalyzed isomerization in the acetolysis medium. Therefore, in order to verify that the products and their ratios were, in fact, those of kinetically controlled solvolyses, those isolated pure were treated with acetic acid and acetic acid-sodium acetate under the same conditions used for the product studies (actually for more than the corresponding ten half-lives). The products were recovered unchanged.<sup>7</sup>

7) It seems likely that such epimerization requires much more severe conditions. For example, treatment of VIII-axOAc in the acetolysis solvent at 150° for 3 hr led to a mixture consisting of 85% VIII-axOAc and 15% VIII-eqOAc. A related example, the epimerization and rearrangement of dibenzobicyclo[3.2.1]octadien-2-ol acetate studied by Stol, *et al.*,<sup>8</sup> required such a strong condition at HClO<sub>4</sub>-CH<sub>3</sub>COOH.

The acetolysis of I-OBs for ten half-lives produced in quantitative yield a mixture consisting of 98% of benzo[3,4]bicyclo[3.2.1]octen-axial-2-ol acetate (VIII-axOAc) and 2% of its epimer VIII-eqOAc. The retained product I-OAc and the inverted product II-OAc were absent. Hydrolysis of both acetates with lithium aluminum hydride, followed by Oppenauer oxidation, afforded the same reported benzo[3,4]bicyclo[3.2.1]octen-2-one, the semicarbazone of which was identified by comparison with an authentic sample.<sup>9</sup> This fact proves the ring system of both acetates. It has been reported in nmr studies of bicyclo[3.2.1]oct-3-en-2-yl,

octen-2-one, the semicarbazone of which was identified by comparison with an authentic sample.<sup>9</sup> This fact proves the ring system of both acetates. It has been reported in nmr studies of bicyclo[3.2.1]oct-3-en-2-yl,

(8) S. J. Cristol, F. P. Parungo, D. E. Plorde, and K. Schwarzenbach, *J. Am. Chem. Soc.*, **87**, 2879 (1965).

(9) We thank Professor W. Baker for providing the sample. Refer to W. Baker and W. G. Leeds, *J. Chem. Soc.*, 974 (1948).

benzo[3,4]bicyclo[3.2.1]octen-2-yl, and dibenzobicyclo[3.2.1]octadien-2-yl derivatives that the eqH<sub>2</sub> shows a coupling constant of 1.4–2.9 Hz with the bridgehead H<sub>1</sub>, whereas the corresponding coupling constant of the axH<sub>2</sub> is 4.3–5.4 Hz.<sup>10–12</sup> Thus the coupling constants, 2.8 and 4.6 Hz, observed for VIII-axOH and VIII-eqOH, respectively, confirmed the configuration of the hydroxyl groups.

Acetolysis of II-OBs led to a nearly quantitative yield of an acetate mixture containing 83% of the retained II-OAc and 17% of the rearranged IX-axOAc.

Vpc demonstrated the absence of the inverted acetate I-OAc and IX-eqOAc. The structure of IX-axOAc was identified with an authentic sample which was prepared, as shown in the following chart, by the *exo* addition of dichlorocarbene (prepared from chloroform and potassium *t*-butoxide) to benzonorbornene, followed by hydrolysis and then hydrogenation. Substantially the same reaction route has been reported by several workers for the synthesis of bicyclo[3.2.1]oct-3-en-2-yl derivatives.<sup>10,12,13</sup> Hydrolysis of the intermediate XIII was indicated by nmr spectroscopy to yield predominantly the ax-allylic alcohol XIV, in which  $J_{1,2}$

is 2.2 Hz. This stereospecific result was similarly observed in the hydrolysis of ax-2,3-dichlorobicyclo[3.2.1]oct-3-ene.<sup>10b,12–15</sup> An authentic sample of IX-eqOAc was prepared by Oppenauer oxidation of IX-axOH, followed by lithium aluminum hydride reduction<sup>17</sup> and then acetylation.

Acetolysis of III-OBs resulted in a mixture consisting of the four compounds, ax- and eq-benzo[3,4]bicyclo[3.2.1]octa-3,6-dien-2-ol acetates (X-axOAc and -eqOAc) and *exo*- and *endo*-benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octen-6-ol acetates<sup>18</sup> (XI-*exo*-OAc and -*endo*-OAc).

(14) A related result has been reported by Cristol in the reaction of dibenzobicyclo[3.2.1]octadien-2-yl cation which reacts from the *exo* (quasi-ax) side reversibly most rapidly to give (generally) the *exo* product as that of kinetic control.<sup>9</sup>

(15) Results of this kind are reasonable since in allylic cyclohexenyl systems formation and cleavage of quasi-ax bonds is stereoelectronically favored over formation and cleavage of quasi-eq bonds.<sup>16</sup>

(17) The reduction gave IX-eqOH and IX-axOH in a ratio of 3:2.

At ten half-lives, the relative peak areas of X-axOAc, X-eqOAc, XI-*endo*-OAc, and XI-*exo*-OAc on vpc analysis were 72, 11, 7, and 10, respectively. However,

because only a capillary vpc column could separate X-eqOAc and XI-*endo*-OAc, the errors in these product ratios will be approximately twice as large as those in the other cases. Confirmatory evidence for the indicated structures was provided by detailed examination of their nmr spectra, as described in the following section. In addition, the main products from catalytic reductions of X-axOAc and X-eqOAc over PtO<sub>2</sub> were VIII-axOAc and VIII-eqOAc, respectively. These results chemically confirmed structures of the X derivatives.

Complete rearrangement to the benzo[6,7]bicyclo[3.2.1]octa-3,6-dien-2-yl system XII was observed in the acetolysis of IV-OBs. The product for ten half-lives was an 83:17 mixture of XII-axOAc and XII-eqOAc. The structures of the products were convincingly established by the nmr spectra, mentioned below. The structure of XII-axOAc was also chemically confirmed

by the predominant formation of IX-axOAc on catalytic reduction over PtO<sub>2</sub>.

It is particularly significant that careful search by vpc demonstrated the absence of the retained and inverted products in the acetolysis mixtures of III-OBs and IV-OBs.

**Discussion of Solvolysis Results.** Relevant solvolytic studies have been reported by Walborsky, *et al.*,<sup>19</sup> and Goering, *et al.*,<sup>16b,20</sup> for the bicyclo[2.2.2]octyl system V, by Goering, *et al.*, for the *endo*-2-bicyclo[2.2.2]octenyl system VI, by LeBel, *et al.*,<sup>21</sup> and Fraser, *et al.*,<sup>22</sup> for the *exo*-2-bicyclo[2.2.2]octenyl system VII, and by Cristol and his co-workers<sup>23</sup> for the dibenzo[2.2.2]octadienyl system. With these available data, the present results build up an almost complete set of

lytic behavior of bicyclo[2.2.2]octyl and its related derivatives. The ratios  $k_{\text{AcOH}}/k_{\text{EtOH}} = 2.6$  at 35° in the solvolyses of I-OBs and II-respectively (footnotes in Table I), suggest thatophilic participation by solvent is not important; in other words, acetolysis<sup>24</sup> (probably also ethanolysis) involves carbonium ion intermediates.<sup>25</sup>

rates in acetolyses of dehydronorborn- and norbornen-2(*endo*)-yl brosylates drop to 0.022/0.002 that of norborn-2(*endo*)-yl brosylate.<sup>26-28</sup> In contrast, the rates of VI-OBs and I-OBs were five greater than and nearly equal (a factor of 0.92) to those of V-OBs, respectively. This indicates that the double bond affects the *endo*-norbornenyl and -octenyl solvolyses differently. However, the fact that their ratios, 0.002 and 5.0:0.92, are in the same order of magnitude means that the relative effect of a double bond on the benzene ring is almost the same in each of the cases.<sup>29</sup>

products in the acetolysis of I-OBs, 98% VIII-*ax*-OAc and 2% VIII-*eq*-OAc, are comparable with those in the acetolysis of VI-OBs.<sup>16b</sup> Thus, the combined kinetic and stereochemical results are consistent with the formation of the carbonium ion A stabilized by anchimeric resonance, as discussed in the case of VI-OBs. Stereospecific conversion of A to VIII-*ax*-OAc would be explained as in similar cases;<sup>8,15,16b</sup> that is, A electronically favors formation of quasi-*ax* over *eq* bonds. Lithium aluminum hydride reduction of the corresponding 2-one leads to an 8:2 mixture of VIII-*ax*-OH and VIII-*eq*-OH. Since the stereochemical results for the reduction of bridged cyclic ketones by lithium aluminum hydride are controlled by "steric approach of hydride,"<sup>30,31</sup> the major formation of VIII-*ax*-OH may

suggest that the *ax* side is sterically more hindered. It is indicated, therefore, that collapse of the ion A to products is predominantly taking place from the sterically unfavorable direction.

The 2.6-fold increase in the rate of II-OBs (relative to V-OBs) and the small *exo:endo* rate ratio (a factor of 2.8) are insufficient values to propose a homobenzylic ion B as an intermediate, in which anchimeric assistance from  $\pi$  electrons in the benzene ring is significantly provided. Similarly, by such a small value as the 2.9-fold increase in the case of IV-OBs, assistance from the benzene ring cannot be considered. The *exo:endo* rate ratios in the norbornen-2-yl and benzonorbornen-2-yl arenesulfonates are both in the same order of magnitude (at 25°, 7000<sup>26</sup> and 15,000,<sup>27</sup> respectively). Thus, the nonclassical ion C analogous to B has been suggested for the solvolysis of benzonorbornen-2-yl arenesulfonate.<sup>27,32</sup> The rate-increasing effect of the double bond in VII-OBs has been reported as a factor of 260 and the *exo:endo* rate ratio thus obtained is 52, so that considerable anchimeric assistance by the double bond is demonstrated.<sup>21</sup> Therefore, the present results are in striking contrast.

The kinetic results and the stereochemical findings (the lack of I-OAc and IX-*eq*-OAc) in the acetolysis of II-OBs could be rationalized by postulating either a nonclassical cation D which may involve participation of the C<sub>1,6</sub>-methylene bond, but not that of the benzene  $\pi$  electrons, or a rapidly equilibrating set of classical ions E and F which simulate D. A windshield-

wiper effect in this equilibrating set can be invoked in order to explain the observed stereochemistry.<sup>33</sup> It should be noted that the results in the lithium aluminum hydride reduction of the 2-one<sup>17</sup> indicate little difference in the steric factors between *ax* and *eq* approach to the open C<sub>2</sub> carbonium ion, if formed.<sup>34</sup>

In contrast to the acetolyses of the octenyl derivatives, no stereospecific result was obtained in the reactions of the octadienyl derivatives. From the kinetic data, especially from the small rate ratio  $k_{\text{III-OBs}}/k_{\text{IV-OBs}} = 3.8$ , it can be argued that little, if any, participation by the double bond is being exerted in the acetolysis of III-OBs. Stereochemical results preclude the participation of the classical [2.2.2]dienyl ion G as an intermediate. Absence of products having the [2.2.2] skeleton and lack of stereospecificity also make nonclassical intermediates such as H, I, and J or a rapid and reversible equilibrium between classical ions K and L unsatisfactory. The

(33) H. C. Brown, "The Transition State," Special Publication No. 16, The Chemical Society, London, 1962, pp 140-158, 174-178.

(34) It has been reported by A. A. Yousef, M. E. Baum, and H. M. Walborsky, *J. Am. Chem. Soc.*, 81, 4709 (1959), that LiAlH<sub>4</sub> reduction of bicyclo[3.2.1]octan-2-one give the corresponding *eq*- and *ax*-2-ols in a ratio of 9:1 and the *eq* is thermodynamically more stable than the *ax*.

S. Winstein, *et al.*, *J. Am. Chem. Soc.*, 79, 4146 (1957); 75, 1477, 2700 (1951).

It has been shown that internal return may be an important factor in solvolysis. See S. Winstein, E. Clippinger, A. H. Fainberg, R. Heck, C. Robinson, *ibid.*, 78, 328 (1956). However, any ion-pair return might be involved in the acetolysis of I-OBs, III-OBs, and IV-OBs but not affect the solvolysis rate (*i.e.*, in these cases the solvolysis rate depends on the ionization rate). This is because the expected product-ion-pair return, that is, VIII-*ax*-OBs for I-OBs, X-*ax*-OBs and OBs for III-OBs, and XII-*ax*-OBs for IV-OBs, would solvolyze rapidly. For a similar situation, see A. H. Fainberg and S. Winstein, 78, 2767 (1956); footnote 23 in ref 20b; footnote 16 in ref 12 in S. J. Cristol, W. K. Seifert, D. W. Johnson, and J. B. F. *Am. Chem. Soc.*, 84, 3918 (1962). In the remaining case, that is, acetolysis of II-OBs, ion-pair return would conceivably give the starting II-OBs and IX-*ax*-OBs. IX-*ax*-OBs might be expected to solvolyze more slowly than II-OBs. However, careful first-order experiments give no evidence for this expectation.

S. Winstein, H. M. Walborsky, and K. Schreiber, *ibid.*, 72, 5795

(3) D. Bartlett and W. P. Giddings, *ibid.*, 82, 1240 (1960). The constant at 25° originally reported in this paper was  $1 \times 10^{-6}$ . However, the recalculation by H. C. Brown and G. L. Trille d it to  $5.1 \times 10^{-6} \text{ sec}^{-1}$  (a private communication from Professor Brown). We confirmed the recalculation. Therefore, the factor reported widely in reviews is corrected to 0.002, and also the *exo:endo* ratio in the acetolysis of benzonorbornen-2-yl brosylates is corrected to 15,000 from 7500.

(a) For a review, see J. A. Berson in "Molecular Rearrangements," P. de Mayo, Ed., Interscience Publishers, Inc., New York, N. Y., 1953; (b) for summarized data, see ref 2b.

(3) From this consideration and the rate constant for IV-OBs, we have the rate constant of  $\sim 4 \times 10^{-6} \text{ sec}^{-1}$  at 25° for the acetolysis of bicyclo[2.2.2]octadien-2-ol brosylate. This value is compatible with that obtained by Cristol and Mohrig. According to a private communication from Professor S. J. Cristol, they obtained an approximate constant of  $2 \times 10^{-6} \text{ sec}^{-1}$  for the corresponding tosylate at water-acetic acid (3.6:96.4 mole %) solvent (Ph.D. Dissertation Mohrig, University of Colorado, 1963).

<sup>a</sup> Obtained in CCl<sub>4</sub>. Values in parentheses are data obtained in C<sub>6</sub>D<sub>6</sub>. Peak multiplicities are represented by s (singlet), d (doublet), t (triplet), q (quartet), and m (multiplet). <sup>b</sup> Absolute values. <sup>c</sup> Obtained from Dreiding models. Accuracies are ±2°. <sup>d</sup> Obscured.

combination of kinetic and stereochemical behavior can be accommodated by the direct formation of an equilibrium mixture containing the benzylic cation M and the

cyclopropylcarbinyl cation N. The predominant formation of X-axOAc would be accounted for with a stereoelectronic factor as in the above-mentioned case.

As in the case of I-OBs, the direct formation of the classical cation O, stabilized by allylic resonance and not involving participation from the benzene ring, can accommodate all results from IV-OBs.

A summary of related data shows that the relative rates at 25° in acetolyses are for norbornyl, dehydronorbornyl, and benzonorbornenyl *exo*-2-brosylates, 1, 0.5, and 0.08; for V-OBs, VII-OBs, and II-OBs, 1, 260, and 2.6; for I-OBs, III-OBs, and dibenzobicyclo[2.2.2]octadienyl-OBs, 1, 12, and ~0.5.<sup>20</sup> In each series, ratios of relative rates for the dehydro and the benzo derivatives (0.5:0.08 = 6, 260:2.6 = 100, and 12:0.5 = 24) express the relative effectiveness of double

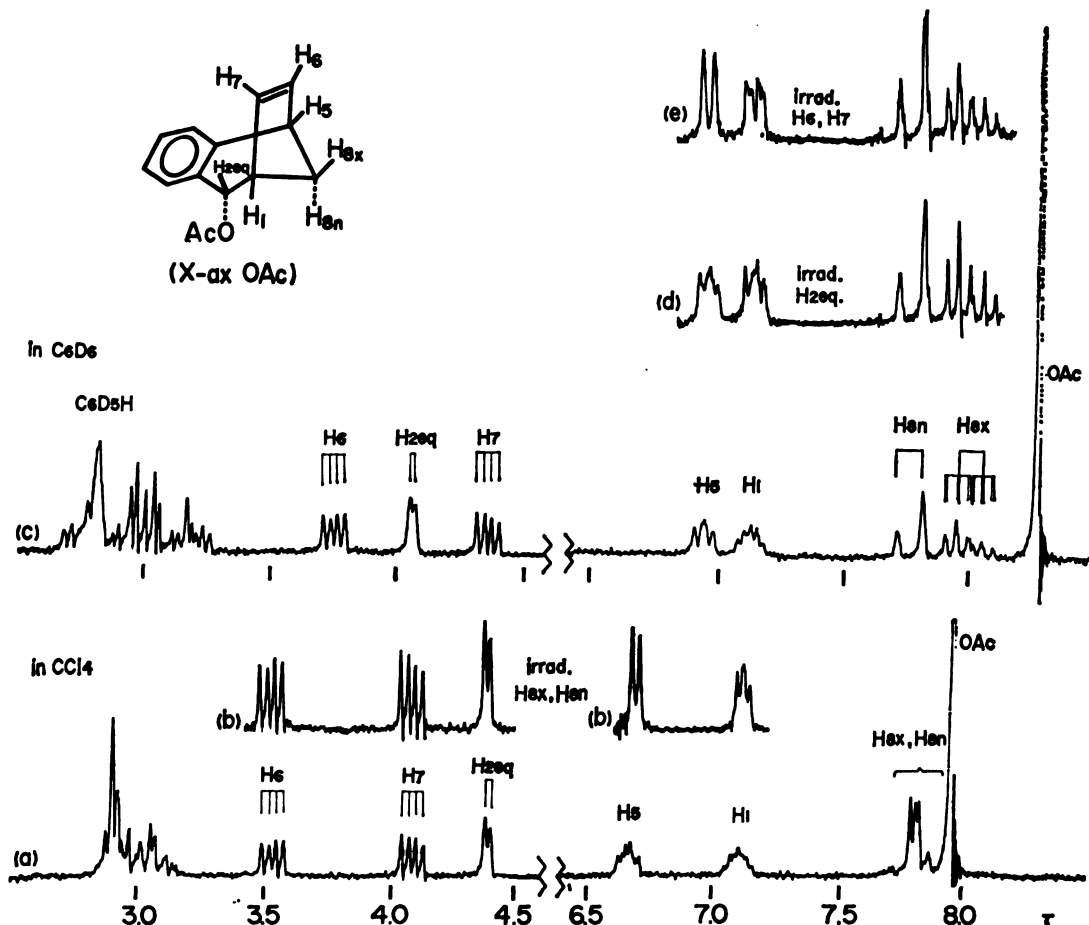

Figure 1. Nmr, nmtr, and nmtr spectra of X-axOAc in  $\text{CCl}_4$  and  $\text{C}_6\text{D}_6$  at 100 MHz. (Spectra shown in b, d, and e were run at increased resolutions.)

ends *vs.* benzene rings for participation. Thus, it is clear that the most flexible [2.2.2]octenyl system can achieve the most favorable conformation for participation (the factor of 100). The least participation (the factor of 6) is indicated in the rigid norbornenyl system. However, the present study cannot rationalize the origin of the rate of V-OBs which is 49 times faster than that of cyclohexyl brosylates.

**Nmr Spectra of Benzo[3,4]bicyclo[3.2.1]octa-3,6-dien-1(X), Benzo[6,7]bicyclo[3.2.1]octa-3,6-dien-2-yl (XII), Benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octen-6-yl (XI) Derivatives.**

Investigations of the nmr spectra of the six diastereomers X–XII by using double and triple resonance (nmr and nmtr) techniques and the solvent effect of benzene<sup>25</sup> at 100 MHz provided evidence for their structures. The nmr spectra with some spin-decoupling experiments are shown in Figures 1–6. In Table II listed the chemical shifts and the coupling constants (observed solute values) obtained. The procedure for the structural assignments of these compounds is described in the Experimental Section.

The fact that the two bridgeheads  $\text{H}_1$  and  $\text{H}_8$  are vicinally coupled to the olefinic  $\text{H}_6$  and  $\text{H}_7$  in the two compounds X indicates that these compounds belong to the

benzo[3,4]bicyclo[3.2.1]octa-3,6-diene system. Applying the Karplus correlation<sup>27</sup> to the obtained  $J_{1,2}$  values,<sup>10–12</sup> we confirmed that the acetoxyl at  $\text{C}_2$  in X-axOAc and X-eqOAc has an ax and an eq configuration, respectively. Among long-range spin couplings expected by analogy with bicyclo[2.2.1]heptenes,<sup>28</sup> a  $J_{\text{ax},7}$  of about 0.3 Hz and very small  $J_{6,8n}$  and  $J_{7,8n}$  were only observed. The overlapping of the back-side lobe of the  $\sigma$  orbital of  $\text{H}_{8n}$  with  $\pi$  orbitals of the double bond<sup>29</sup> might be slight in this system. A long-range  $J_{2\text{eq},8x}$  of 0.8 Hz was, however, clearly established, as expected from the “W-letter” rule.<sup>28</sup>

Decoupling experiments on the two compounds XII showed that only one bridgehead  $\text{H}_8$  is vicinally coupled to the one olefinic  $\text{H}_4$ . This fact implies that these compounds belong to the benzo[6,7]bicyclo[3.2.1]octa-3,6-diene system. The observed  $J_{1,2}$  likewise determined the configurations of the acetoxyls at  $\text{C}_2$  in XII-axOAc and XII-eqOAc as ax and eq, respectively. The allylic  $J_{2\text{ax},4}$  (2.3 Hz) in XII-eqOAc was greater than  $J_{2\text{eq},4}$  (1.0 Hz) in XII-axOAc. This indicates that, as suggested by the molecular models,  $\text{H}_{2\text{ax}}$  has more ax character than  $\text{H}_{2\text{eq}}$ .<sup>28</sup> Jefford, *et al.*,<sup>30</sup> reported that similar allylic  $J_{2,4}$  cannot be observed in several *exo*-

ascribed to the “W-letter” rule.<sup>38</sup> Long-range  $J_{4,8n}$  and  $J_{2eq,3n}$  in XII-axOAc and  $J_{4,8n}$  in XII-eqOAc were also observed.<sup>39</sup>

The present experiments on X and XII indicated negligibly small magnitudes for allylic ( $J_{1,6}$  and  $J_{5,7}$

is minimized. It should be further noted that  $J_{4,4}$  (9.5 Hz) and  $J_{4,5}$  (ca. 6.5 Hz) in XII are greater than  $J_{6,7}$  (5.8 Hz) and  $J_{1,7}$  or  $J_{6,8}$  (ca. 2.9 Hz) in X, respec-

(40) F. P. Johnson, A. Melera, and S. Sternhell, *Australian J. Chem.*, 19, 1523 (1966).

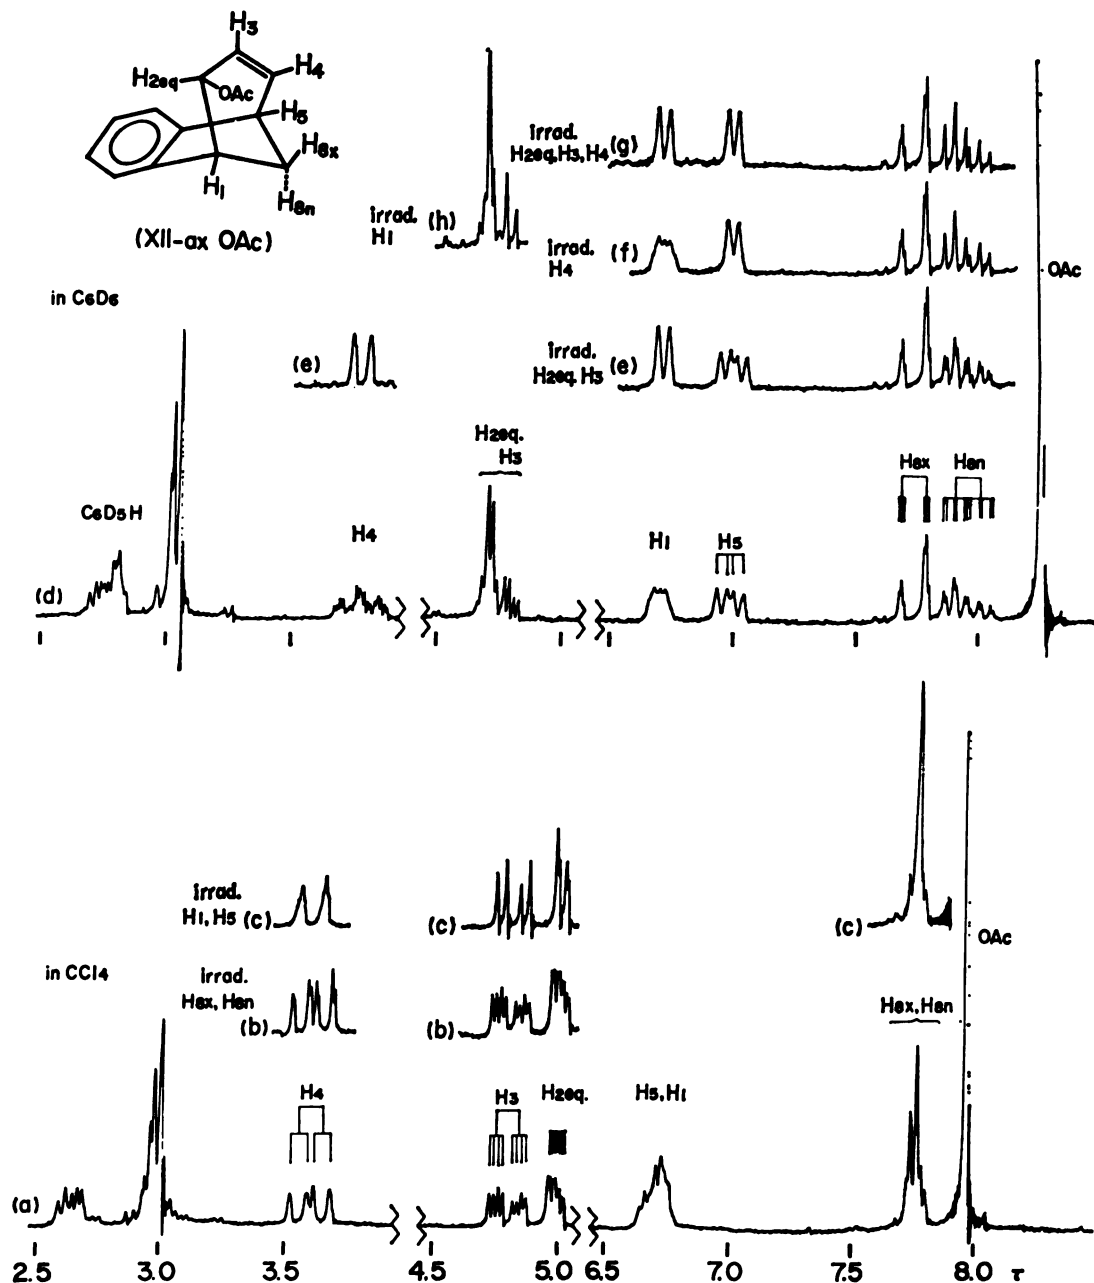

Figure 3. Nmr, nmrd, and nmtr spectra of XII-axOAc in  $\text{CCl}_4$  and  $\text{C}_6\text{D}_6$  at 100 MHz.

tively, and that  $|J_{8x,8n}|$  (ca.  $\approx 10$  Hz) is not so small. The former fact can be derived and explained by the difference in the ring size;<sup>41</sup> the latter fact implies that the methylene bridges in X and XII are relatively less strained than in the case of bicyclo[2.2.1]heptenes, in which  $J$  values between the two bridge methylene protons are about  $\approx 8.5$  Hz.<sup>42</sup>

For the structures of the two remaining products XI, it is possible to assume the alternative ring systems, benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octene (XI) and benzo[3,4]tricyclo[3.1.1.1<sup>2,6</sup>]octene (XV). Although the spectrum of XI-*exo*-OAc in  $\text{CCl}_4$  (see Figure 5a) shows very complicated signals at  $\tau$  7.8 and 8.0, in  $\text{C}_6\text{D}_6$  the signals appear

fairly separated. The spectrum showed only one signal, assignable to one bridgehead proton; this is inconsistent with XV having two bridgehead protons on the benzylic

carbons. On the other hand,  $\text{H}_2$  in XI is benzylic and also cyclopropyl; therefore it can be anticipated to appear at a higher field than at an ordinary position. Further, LeBel and Huber<sup>21</sup> have reported that  $\text{H}_6$  in tricyclo[3.2.1.0<sup>2,7</sup>]octan-6(*endo*)-ol *p*-nitrobenzoate (XVI) (*endo* is for cyclopropyl) appears as a singlet because both the dihedral angles between  $\text{H}_{6x}$  and  $\text{H}_6$ ,  $\text{H}_7$  protons are close to  $80^\circ$ . The broad singlet signal in XI-*exo*-OAc at  $\tau$  5.55 in  $\text{CCl}_4$  (at  $\tau$  5.35 in  $\text{C}_6\text{D}_6$ )

Figure 4. Nmr and nmr spectra of XII-eqOAc in  $\text{CCl}_4$  and  $\text{C}_6\text{D}_6$  at 100 MHz.

suggests an *exo* configuration for the acetoxyl. The nmr and nmr experiments (see Figure 5 and Experimental Section) confirmed the structure of XI-*exo*-OAc from various approaches. The fact that  $J_{\text{H}_{4\text{ax}},\text{H}_{4\text{eq}}} (= 11.6 \text{ Hz})$  falls in a range of magnitudes expected from geminal couplings between methylene protons on a normal  $\text{sp}^3$  carbon indicates, in accord with the above assignment, that the  $\text{C}_8$  orbital is not highly strained.

Similarly, the nmr and nmr experiments on XI-*endo*-OAc (see Figure 6 and Experimental Section) led us to conclude that this compound is an epimer of XI-*exo*-OAc. An important change in the spectrum of this compound from that of XI-*exo*-OAc is the appearance of a broad quartet due to  $\text{H}_{4\text{ax}}$  ( $J = 5.0$  and  $3.0 \text{ Hz}$ ),<sup>21</sup> instead of the broad singlet due to  $\text{H}_{4\text{eq}}$  (see the dihedral angles in Table II).

Except  $J_{7,8\text{a}}$  and  $J_{8\text{a},8\text{b}}$ , many long-range couplings were observed, as expected from the ring system of XI according to "W-letter rule."<sup>22</sup> Besides the expectation,  $J_{6\text{a},7\text{a}}$  and  $J_{6\text{a},8\text{a}}$  were obtained, though less than or

equal to 0.2 Hz. It is interesting to note that  $J_{1,3}$  and  $J_{2,7}$  (7.0 Hz) are not equal to  $J_{1,7}$  (5 Hz). This finding may suggest that the strain at  $\text{C}_1$  and  $\text{C}_7$  is different from that at  $\text{C}_2$ .

#### Experimental Section<sup>43</sup>

Properties and analyses of the new compounds prepared in the present study are summarized in Table III.

**Materials.** For the preparation of III-OH and IV-OH the reduction of benzobicyclo[2.2.2]octadien-2-one<sup>1</sup> was carried out with 4 equiv of lithium aluminum hydride in anhydrous tetrahydrofuran. The usual work-up, followed by separation using elution chromatography over silica gel (Woelm neutral, added with 5% of  $\text{H}_2\text{O}$ ), gave pure samples of III-OH and IV-OH in a ratio of 7:3.

**Kinetic Measurements.** The kinetic procedure for the acetoxylation studies was essentially the same as that employed previously.<sup>2,3</sup> In all cases the initial concentration of brosylate was approximately 0.03 M. The reactions were carried out in glacial acetic acid

(43) Melting points were taken by capillary and are corrected. Boiling points are uncorrected. Ultraviolet spectra were recorded on a Beckman DK-2 spectrometer.

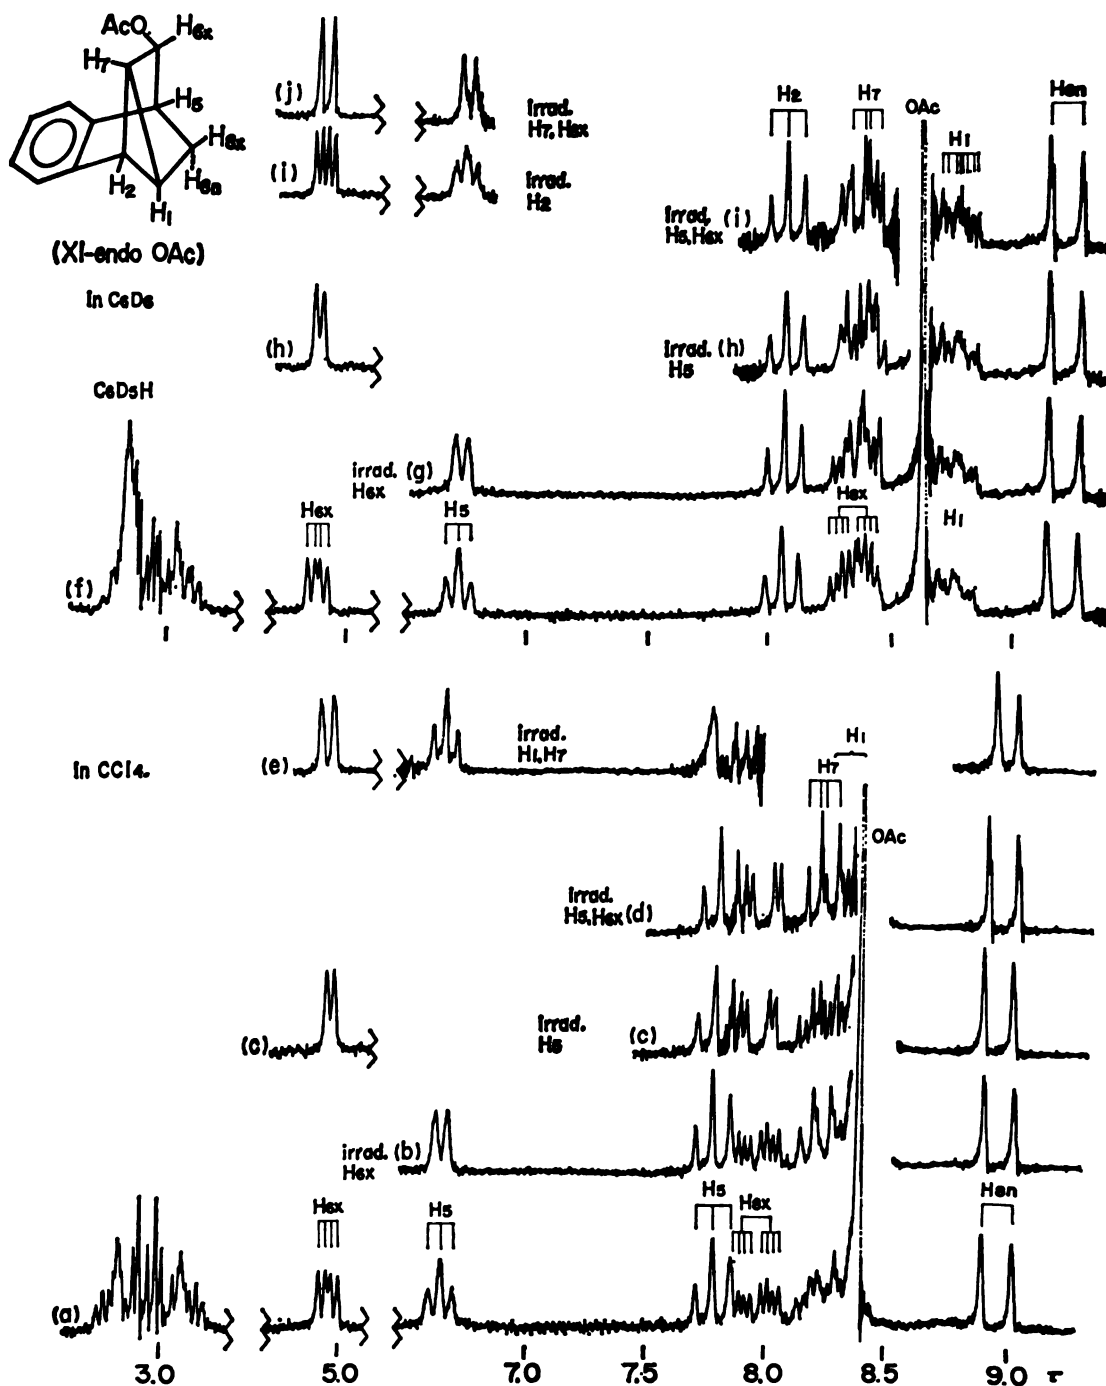

Figure 5. Nmr, nmtr, and nmtr spectra of XI-exo-OAc in CCl<sub>4</sub> and C<sub>6</sub>D<sub>6</sub> at 100 MHz.

aining an equivalent of sodium acetate and 1 wt % of acetic anhydride. Rate constants were determined by the infinity titer method. Usually, ten aliquots, 2 ml in volume, were periodically drawn, run into 20 ml of cooled dioxane, and titrated immediately with 0.06 M standard perchloric acid solution. Infinity titers were obtained after at least ten half-lives. In all cases observed infinity titers were within  $\pm 2\%$  of the calculated values.

The ethanolyses were carried out in anhydrous ethanol. They were followed by titrating usually ten aliquots, 2 ml in volume, which were quenched by adding to 20 ml of ice-cold acetone, with standard solution of 0.006 M sodium methoxide in mixed benzene and methanol (1:3). A methanol solution of methyl red bromocresol green was used as the indicator.

**Isolation of Acetolysis Products.** The acetolysis solution was allowed to remain in a constant temperature bath for ten half-lives of each of the brosylates, concentrated by distilling the acetic acid, treated with ice-water, and extracted four times with pentane. The pentane solution was washed with aqueous sodium carbonate and dried. After removal of the solvent, the residue was subjected to analytical and preparative vpc.

**Analytical Vapor Phase Chromatography.** A standard column, 2 m  $\times$  6 mm, of stainless-steel tubing was employed with helium as a carrier gas in a Hitachi gas chromatograph Model F-6. The column was packed with 10 wt % diethylene glycol succinate polymer on 30-60 mesh Chromosorb W. The retention times of I-OAc, II-OAc, VIII-axOAc, VIII-eqOAc, and IX-axOAc were 16.5,

**Figure 6.** Nmr, nmdr, and nmtr spectra of XI-*endo*-OAc in CCl<sub>4</sub> and C<sub>6</sub>D<sub>6</sub> at 100 MHz.

18.5, 19.2, 17.5, and 13.5 min, respectively, at 200° with 1.5 kg/cm<sup>2</sup> of He. Those of X-axOAc, X-eqOAc, XI-*endo*-OAc, and XI-*exo*-OAc were 15.0, 18.0, 18.0 (overlapped), and 25.0 min, respectively, at 190° with 1.5 kg/cm<sup>2</sup> of He. Capillary vpc on a 45-m Golay Z-45 at 125° with 1.0 kg/cm<sup>2</sup> of He showed separated peaks at the retention time of 10.5 for X-eqOAc and 11.0 for XI-*endo*-OAc. The retention times of III-OAc, IV-OAc, XII-axOAc, and XII-eqOAc were 15.2, 18.3, 16.0, and 18.0 min, respectively, at 190° with 1.5 kg/cm<sup>2</sup>.

**Preparative vapor phase chromatography** was carried out (a) on a Hitachi gas chromatograph Model F-6, equipped with a 2 m  $\times$  21 mm stainless-steel tubing column packed with 10 wt % of diethylene glycol succinate polymer on 30-60 mesh Chromosorb W (column A); (b) on a Yanagimoto gas chromatograph Model GCG-3D, equipped with a 5 m  $\times$  14 mm stainless-steel tubing column packed with 5 wt % diethylene glycol succinate polymer on the same support (column B). The retention times were 15.2 and 13.0 min, respectively (200° of column B and 300 cc/min of He),

for II-OAc and IX-*ax*OAc; 19.5, 23.5, 23.5 (overlapped), and 32.0 min, respectively (210° of column A and 600 cc/min of He), for X-*ax*OAc, X-*eq*OAc, XI-*endo*-OAc, and XI-*exo*-OAc; 20.5 and 22.5 min, respectively (210° of column A and 500 cc/min of He), for XII-*ax*OAc and XII-*eq*OAc.

**Benzo[3,4-b]cyclo[3.2.1]octen-2-one.** A solution of 72 mg of VIII- $\alpha$ -OH, 53.6 mg of benzoquinone, and 203.6 mg of aluminum *t*-butoxide in 7 ml of benzene was refluxed overnight. The mixture was washed with dilute sulfuric acid and then with aqueous sodium hydroxide until the inorganic layer was colorless. The benzene solution was dried and evaporated, and the residue was distilled to give 59 mg of the ketone at 132–135° (5 mm),  $n_D^{25}$  1.5684 (lit.<sup>1</sup> bp 162–163° (23 mm),  $n_D^{25}$  1.577),  $\lambda_{\max}^{\text{KOH}}$  249 m $\mu$  ( $\epsilon$  11,600) and 293 (2310).

*Anal.* Calcd for  $C_{12}H_{11}O$ : C, 83.69; H, 7.02. Found: C, 83.59; H, 7.14.

**Axial 2,3-Dichlorobenzo[6,7]bicyclo[3.2.1]octa-3,6-diene (XIII).** To a stirred solution of 121 g of benzonorbornene in 500 g of dry

form, maintained at 0° under nitrogen, was added 175 g of sium *n*-butoxide during 6 hr. The mixture was added to water neutralized with hydrochloric acid. The organic layer was and distilled to remove *n*-butyl alcohol, chloroform, and most unchanged benzonorbornene. Further distillation under pressure, followed by elution chromatography, gave 10 g II, bp 124–125° (2 mm),  $n_D^{20}$  1.5963, nmr in CCl<sub>4</sub>: four aromatic H at  $\tau$  2.6–3.0 (m), one vinyl H at 3.61 (d), one C<sub>2</sub> H at 5.74 (d), one C<sub>1</sub> bridgehead H at  $\sim$ 6.35 (m), one C<sub>2</sub> bridgehead H at  $\sim$ 6.60 (m), two C<sub>3</sub> H at 7.4–8.0 (m),  $J_{1,2} = 2.1$ ,  $J_{1,5} = 6.8$  Hz.

*u.* Calcd for C<sub>13</sub>H<sub>10</sub>Cl<sub>2</sub>: C, 64.02; H, 4.48. Found: C, 63.32; H, 4.64.

**1-Chloro-2(axial)-hydroxybenzo[6,7]bicyclo[3.2.1]octa-3,6-diene.** A suspension of 2.7 g of XIII, 4.0 g of calcium carbonate, of tetrahydrofuran, and 40 ml of water was refluxed under nitrogen for 51 hr. The mixture was extracted with ether. Evaporation of the ether gave 2.2 g of XIV, mp 119–120°; nmr in CCl<sub>4</sub>: four aromatic H at  $\tau$  2.6–3.0 (m), one vinyl H at 3.64 (d), one C<sub>2</sub> H at 6.11 (d), two C<sub>1,5</sub> bridgehead H at  $\sim$ 6.5 (m), two C<sub>3</sub> H at  $\sim$ 7.7 (m),  $J_{1,2} = 2.2$  and  $J_{4,5} = 7.2$  Hz.

*u.* Calcd for C<sub>12</sub>H<sub>10</sub>ClO: C, 69.74; H, 5.37; Cl, 17.15. d: C, 70.09; H, 5.76; Cl, 17.32.

**Hydrogenation of XIV.** A solution of 127 mg of XIV in 3 ml of tetrahydrofuran and 0.7 ml of 1.0 *N* sodium hydroxide was hydrogenated over palladium-charcoal. The hydrogen uptake was 29.0 ml. The usual work-up left 98 mg of crude IX-axOH. Purification was performed by preparative vpc: 10% diethylene glycol succinate polymer on Chromosorb W, column temperature 185°, 10 cc/min, retention time 18.5 min, nmr in CCl<sub>4</sub>: four aromatic H at  $\tau$   $\sim$ 2.9 (m), one CHOH at 6.13 (m), two bridgehead H 6.9 (m), six H at 7.5–9.0; nmr of the acetate (IX-axOAc) in CDCl<sub>3</sub>: four aromatic H at  $\tau$   $\sim$ 2.9 (m), one CHOH at 5.17 (m), two bridgehead H at  $\sim$ 6.8 (m), six H at 7.6–9.1, three CH<sub>2</sub>CO 7.0.

**Nmr Measurements.** Nmr spectra were taken with a Varian A spectrometer (60 MHz), calibration of which was checked by the usual side-band method, and/or a Varian HA-100 spectrometer operating at a 100-MHz field in the frequency-swept and tetramethylsilane (TMS) locked mode. The calibration of 100-MHz spectra was made by using a Hewlett-Packard HP-5212A electronic reference. Accuracies of chemical shifts and coupling constants are  $\pm$  0.01 and  $\pm$  0.1 Hz, respectively. The spectra were recorded by using about 2–5% (w/v) solutions of samples in CCl<sub>4</sub> or C<sub>6</sub>D<sub>6</sub> containing TMS as an internal reference. Nmr and nmtr experiments were made by using the HA-100 spectrometer and two Hewlett-Packard HP-200ABR audio-oscillators in frequency-swept operation.

**Procedure for the Nmr Spectral Assignments of Benzo[bicyclooctadiene Derivatives X and XII.** The spectrum of X-axOAc in CCl<sub>4</sub> (Figure 1a) shows a singlet at  $\tau$  7.96 due to the acetoxy protons, a doublet at about  $\tau$  7.8 assignable to the bridge methylene H<sub>2,3</sub>, two multiplets at  $\tau$  7.11 and 6.66 due to the bridgehead H<sub>1</sub> and H<sub>5</sub>, two quartets at  $\tau$  4.10 and 3.53 arising from the olefinic protons H<sub>7</sub> and H<sub>4</sub>, a doublet at  $\tau$  4.38 corresponding to H<sub>6</sub>, and complex multiplets at lower fields due to benzene ring protons. In this spectrum, the signal positions of H<sub>2,3</sub> and H<sub>6</sub> are so close that their assignments are difficult and the signals of H<sub>1</sub> and H<sub>5</sub> appear as second-order patterns. Double irradiation at the center of resonance frequencies of H<sub>2,3</sub> and H<sub>6</sub> (Figure 1b) made the two quartets at  $\tau$  3.53 ( $J = 5.8$  and 3.1 Hz) and 4.10 ( $J = 5.8$  and 2.7 Hz) and a doublet at  $\tau$  4.38 ( $J = 2.0$  Hz) relatively sharper, showing the absence of weak long-range couplings, and changed the multiplet at  $\tau$  7.11 into a quartet ( $J = 2.7$  and 2.0 Hz), which was assignable to H<sub>1</sub>, and the multiplet at  $\tau$  6.66 into a doublet ( $J = 3.1$  Hz), which might be due to H<sub>5</sub>. On double irradiation on H<sub>2,3</sub>, one olefinic proton signal at  $\tau$  3.53 collapsed to a doublet ( $J = 5.8$  Hz), which was therefore assigned to H<sub>4</sub>. Decoupling of H<sub>1</sub> resulted in splitting of the H<sub>7</sub> signal at  $\tau$  4.10 into a doublet ( $J = 5.8$  Hz) and the doublet at  $\tau$  4.38 into a somewhat broad singlet, assignable to H<sub>6</sub> on the basis of its  $J_{1,2}$  value.<sup>10–12</sup> These experiments showed that no appreciable  $J_{1,4}$ ,  $J_{5,7}$ , and benzylic couplings<sup>28,42</sup> are observable. The spectrum in C<sub>6</sub>D<sub>6</sub> (Figure 1c) shows the signals of H<sub>2,3</sub> and H<sub>6</sub> separately as a doublet of triplets ( $J = 10.0$  and 4.7 Hz) and a doublet ( $J = 10.0$  Hz), respectively, as expected from the coupling of benzene.<sup>30,38</sup> These assignments were made according to Karplus correlation<sup>32</sup> (see the dihedral angles in Table II). Double irradiation on H<sub>2,3</sub> ( $\tau$  4.10) made each H<sub>2,3</sub> signal peak very sharp (Figure 1d). On triple irradiation on H<sub>1</sub> and H<sub>7</sub> (Figure 1e), the H<sub>2,3</sub> peak clearly appeared as a doublet ( $J = 0.8$  Hz), and each

H<sub>6</sub> peak changed into a clear triplet ( $J = 0.5$  Hz). This irradiation also collapsed the H<sub>1</sub> and H<sub>5</sub> signals into a doublet of quartets ( $J = 4.7$ , 2.0, and 0.5 Hz) and a quartet ( $J = 4.7$  and 0.5 Hz), respectively. These nmtr and nmtr spectra proved the presence of a long-range  $J_{2,6,ax}$  of 0.8 Hz.<sup>30,39</sup>

The spectrum of X-eqOAc in CCl<sub>4</sub> (Figure 2a) shows overlapping multiplets at about  $\tau$  6.8 due to H<sub>1</sub> and H<sub>5</sub>. Double irradiation at  $\tau$  6.8 changed two quartets at  $\tau$  3.60 and 4.29 due to the two olefinic protons into two doublets ( $J = 5.8$  Hz) which are coupled to each other, the doublet at  $\tau$  4.04 ( $J = 5.4$  Hz) due to H<sub>2,3</sub> into a singlet,<sup>10–12</sup> a doublet of triplets at  $\tau$  7.74 into a doublet ( $J = 10.3$  Hz), and a doublet at  $\tau$  7.95 ( $J = 10.3$  Hz) into a somewhat sharper signal. This irradiation (Figure 2b) also revealed the presence of a weak long-range coupling between H<sub>1</sub> and one olefinic proton which gave the quartet at  $\tau$  4.29. On each double irradiation on an olefinic proton at  $\tau$  3.60 and the other one at  $\tau$  4.29 (Figures 2c and 2d), a doublet ( $J = 5.0$  Hz) and a quartet ( $J = 5.4$  and 5.0 Hz) clearly arose from the overlapping multiplets at about  $\tau$  6.8, respectively. Triple irradiation on the two olefinic protons resulted in the multiplets changing to the doublet due to H<sub>1</sub> and the quartet due to H<sub>5</sub> simultaneously. This irradiation also made some change in the signals arising from H<sub>2,3</sub> and H<sub>6</sub>. Therefore, the quartets at  $\tau$  3.60 and 4.29 were assigned to H<sub>4</sub> and H<sub>7</sub>, respectively. These observations provided evidence for the structure of X-eqOAc. Applying the Karplus correlation,<sup>32</sup> we reached the assignments such that the doublet of triplets ( $J = 10.3$  and 5.0 Hz) at  $\tau$  7.74 and the doublet further weakly split into triplets ( $J = 10.3$  and *ca.* 0.5 Hz) at  $\tau$  7.95 arise from H<sub>2,3</sub> and H<sub>6</sub>, respectively, from the dihedral angles listed in Table II. Similar nmtr and nmtr experiments on X-eqOAc in C<sub>6</sub>D<sub>6</sub> were made to obtain the same conclusion. As shown in Figure 2e, the signals of H<sub>1</sub> at  $\tau$  6.78 and H<sub>5</sub> at  $\tau$  7.03 are well separated and supported the above assignments.  $J_{1,4}$  and  $J_{5,7}$  are too small to be determined from these examinations. In addition, the long-range  $J_{2,6,q,7}$ ,  $J_{4,8,2,3}$ , and  $J_{7,2,3}$  in X-axOAc and X-eqOAc were found to be weak up to the extent of 0.3 Hz.

The spectrum of XII-axOAc in CCl<sub>4</sub> (Figure 3a) exhibits well-unresolved signals because the differences between the chemical shifts of H<sub>1</sub> and H<sub>5</sub> and of H<sub>2,3</sub> and H<sub>6</sub> are very small. The nmtr spectrum irradiated simultaneously on H<sub>2,3</sub> and H<sub>6</sub> (Figure 3b) showed a distinct octet at  $\tau$  3.60 ( $J = 9.6$ , 6.6, and 1.0 Hz) due to one olefinic proton. On double irradiation at the resonance frequency of the center of the two overlapping multiplets due to H<sub>1</sub> and H<sub>5</sub> (Figure 3c), the signal at  $\tau$  3.60 collapsed to a doublet of triplets ( $J = 9.6$  and 1.0 Hz), a doublet of quartets at  $\tau$  4.80 ( $J = 9.6$ , 3.6, and 1.8 Hz) to a quartet ( $J = 9.6$  and 3.6 Hz) which was therefore assignable to the other olefinic proton signal, a quartet of doublets at  $\tau$  4.99 ( $J = 3.6$ , 2.0, and 1.0 Hz) to a quartet ( $J = 3.6$  and 1.0 Hz), and the signals due to H<sub>2,3</sub> and H<sub>6</sub> to a broad singlet, which implies the difference between their chemical shifts are small. From these results, we can assign the signals at  $\tau$  3.60, 4.80, and 4.99 to H<sub>4</sub>, H<sub>7</sub>, and H<sub>2,3</sub>, respectively, and, accordingly, XII-axOAc belongs to the benzo[6,7]bicyclo[3.2.1]octa-3,6-diene, and conclude from  $J_{1,2}$  of 2.0 Hz that the acetoxy has an *ax* configuration.<sup>11–13,39</sup> Long-range  $J$ 's were determined by nmtr and nmtr experiments in C<sub>6</sub>D<sub>6</sub>, in which the signals of H<sub>2,3</sub> and H<sub>6</sub> as well as those of H<sub>1</sub> and H<sub>5</sub> were well separated, as shown in Figure 3d. A doublet of triplets at  $\tau$  7.75 ( $J = 10.1$  and 0.9 Hz) and a doublet of triplets of doublets at  $\tau$  7.94 ( $J = 10.1$ , *ca.* 4.5, and 1.0 Hz) were respectively assigned to H<sub>2,3</sub> and H<sub>6</sub> from their coupling constants to the bridgehead protons because the models showed that the acute dihedral angle between H<sub>1</sub>(H<sub>5</sub>) and H<sub>2,3</sub> is larger than that between H<sub>1</sub>(H<sub>5</sub>) and H<sub>6</sub> (Table II). The nmtr spectrum irradiated at the resonance frequency of the center of the H<sub>2,3</sub> and H<sub>6</sub> signals (Figure 3e) showed a doublet ( $J = 4.6$  Hz) at  $\tau$  6.69, a doublet at  $\tau$  3.60 ( $J = 6.6$  Hz), an unchanged quartet of multiplets at  $\tau$  6.97 ( $J = 6.6$  and 4.2 Hz), and the H<sub>2,3</sub> and H<sub>6</sub> signals. Decoupling of H<sub>1</sub> (Figure 3f) resulted in the signal at  $\tau$  6.97 changing into a doublet ( $J = 4.2$  Hz) which can be assigned to H<sub>5</sub>, and each peak of the H<sub>2,3</sub> signal changing into single sharp one. Thus, the long-range  $J_{4,8,2,3}$  of 1.0 Hz was confirmed.<sup>39</sup> Triple irradiation on H<sub>2,3</sub>, H<sub>4</sub>, and H<sub>7</sub> that changed the H<sub>1</sub> ( $\tau$  6.69) and H<sub>5</sub> ( $\tau$  6.97) signals into two doublets made it possible to determine  $J_{1,2}$  (4.6 Hz) and  $J_{5,7}$  (4.2 Hz) (Figure 3g). While double irradiation on H<sub>1</sub> did not cause any changes in the signals of H<sub>2,3</sub> and H<sub>6</sub>, a coupling ( $J = 1.8$  Hz) in the signal of H<sub>1</sub> disappeared in the spectrum irradiated on H<sub>1</sub> (Figure 3h). These experiments provided evidence for the long-range  $J_{1,2}$  (1.8 Hz). The second-order patterns of the signals of H<sub>1</sub> and H<sub>5</sub> are due to the close positions of the signals of H<sub>2,3</sub> and H<sub>6</sub>.

The nmr spectra of XII-eqOAc in  $\text{CCl}_4$  and  $\text{C}_6\text{D}_6$  are essentially the same except for the signal positions (Figures 4a and 4f). Decoupling experiments similar to the above revealed signal assignments and all  $J$ 's (Figures 4b-e). These results are consistent with the structure of XII-eqOAc. Long-range  $J$ 's in these compounds are listed in Table II.

**Procedure for the Nmr Spectral Assignments of Benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]octene Derivatives XI.** The spectrum of XI-*exo*-OAc in  $\text{CCl}_4$  (Figure 5a) shows complicated signals due to two protons at about  $\tau$  7.8 and a broad doublet due to two protons at about  $\tau$  8.28, so that the signal assignment was difficult. Moreover, the nmrd spectrum irradiated at  $\tau$  7.00 (a broad doublet signal) also gave no insight, as shown in Figure 5b. However, the appearance of only one signal at  $\tau$  7.00 assignable to the bridgehead proton can exclude the XV structure. Further, a singlet at  $\tau$  5.55 indicates a  $\text{C}_6$  *exo*-acetoxyl<sup>11</sup> in the benzo[3,4]tricyclo[3.2.1.0<sup>2,7</sup>]oct-3-ene system. The spectrum in  $\text{C}_6\text{D}_6$  (Figure 5c) shows all proton signals separated. Double irradiation on a thin triplet at  $\tau$  5.35 assignable to  $\text{H}_{\text{ax}}$  (Figure 5d) made each peak of a doublet at  $\tau$  7.02 due to the bridgehead  $\text{H}_1$  and a multiplet around  $\tau$  8.5 fairly sharp, and caused a quartet of triplets at  $\tau$  8.38 ( $J = 7.0, 5.0$ , and  $1.0$  Hz) to collapse into a quartet of doublets ( $J = 7.0, 5.0$ , and  $1.0$  Hz). On double irradiation at  $\tau$  5.55 ( $\text{H}_1$ ) (Figure 5e), a doublet of quartets at  $\tau$  7.85 ( $J = 11.6, 4.9$ , and  $2.8$  Hz), the quartet of triplets at  $\tau$  8.38, the multiplet at about  $\tau$  8.5, a doublet at  $\tau$  9.06 having some broadening ( $J = 11.6$  Hz), and the thin triplet at  $\tau$  5.35 due to  $\text{H}_{\text{ax}}$  were changed into a doublet of doublets ( $J = 11.6$  and  $2.8$  Hz), a quartet of doublets ( $J = 7.0, 5.0$ , and  $1.0$  Hz), a sharper signal, a doublet of doublets ( $J = 11.6$  and  $0.6$  Hz), and a thin doublet ( $J = 1.0$  Hz), respectively. Triple irradiation on  $\text{H}_1$  and  $\text{H}_{\text{ax}}$  (Figure 5f) gave important changes in the two signals at  $\tau$  8.38 and 8.5; the former collapsed to a distinct quartet ( $J = 7.0$  and  $5.0$  Hz), the lowest field peak of which is overlapped with the acetoxyl signal, whereas the latter multiplet collapsed to a doublet of quartets further split into thin doublets ( $J = 7.0, 5.0, 2.8$ , and  $0.6$  Hz). These decoupling experiments confirmed the assignments given in Figure 5 and determined  $J$ 's in Table II. Dreding models suggest that several long-range  $J$ 's should be found in this ring system, besides  $J_{1,5}$  and  $J_{1,7}$  ( $1.0$  Hz) already obtained, according

to the "W-letter rule."<sup>12</sup> The absence of  $J_{\text{ax},\text{ax}}$  was indicated by no change in the signal shape of  $\text{H}_{\text{ax}}$  suffered from double irradiation on  $\text{H}_{\text{ax}}$ . Double and triple irradiation on  $\text{H}_7$  and  $\text{H}_1$  resulted in changes of the signals of  $\text{H}_{\text{ax}}$ ,  $\text{H}_5$ ,  $\text{H}_{\text{ax}}$ , and  $\text{H}_{\text{ax}}$  (Figures 5g-i), and showed the presence of  $J_{1,\text{ax}}$  ( $0.4$  Hz) and the absence of  $J_{7,\text{ax}}$ . Although we failed to determine the magnitudes of  $J_{5,\text{ax}}$  and  $J_{\text{ax},\text{ax}}$  they may be up to the extent of  $0.2$  Hz.

The spectra of XI-*endo*-OAc in  $\text{CCl}_4$  and  $\text{C}_6\text{D}_6$  (Figures 6a and 6f) show features similar to that of XI-*exo*-OAc in  $\text{C}_6\text{D}_6$ . However, in XI-*endo*-OAc the signals of  $\text{H}_{\text{ax}}$  and  $\text{H}_1$  appear as a quartet having some broadening ( $J = 5.0$  and  $3.0$  Hz) and as a triplet further split into multiplets ( $J = 5.0$  Hz). Decoupling experiments in  $\text{CCl}_4$  (Figures 5b-e) confirmed assignments of the signals and determined the  $J$ 's in Table II. In this case, the signals of  $\text{H}_1$  and  $\text{H}_7$  overlapped. However, triple irradiation on  $\text{H}_1$  and  $\text{H}_{\text{ax}}$  revealed the  $\text{H}_7$  signal. The values of  $J_{1,\text{ax}}$  ( $5.0$  Hz) and  $J_{\text{ax},7}$  ( $5.0$  Hz) indicate an *endo* configuration<sup>11</sup> for the acetoxyl (see the dihedral angles in Table II). Similar nmrd and nmtr experiments in  $\text{C}_6\text{D}_6$  (Figures 5g-j) also confirmed the assignments and  $J$ 's. Here, the signals of  $\text{H}_7$  and  $\text{H}_{\text{ax}}$  overlapped. Double irradiation on  $\text{H}_1$  and on  $\text{H}_7$  and  $\text{H}_{\text{ax}}$ , respectively, indicated the presence of  $J_{2,\text{ax}}$  ( $0.4$  Hz) and  $J_{\text{ax},\text{ax}}$  ( $\leq 0.2$  Hz). However, we could not determine the magnitudes of  $J_{1,5}$  and  $J_{7,\text{ax}}$ .

**Nmr of Benzo[3,4]bicyclo[3.2.1]octene Derivatives in  $\text{CCl}_4$ .** The spectrum of VIII-axOH showed four aromatic H at  $\tau$  2.6-3.0 (m), one CHOH at 5.73 (d), two bridgehead H at 6.94 (m) and 7.47 (m), eight H at 7.9-9.1, and  $J_{1,2} = 2.8$  Hz. The spectrum of VIII-eqOH showed four aromatic H at  $\tau$  2.7-3.4 (m), one CHOH at 5.24 (d), two bridgehead H at 7.12 (m) and 7.55 (m), eight H at 8.0-8.8, and  $J_{1,2} = 4.6$  Hz. The CHOH in VIII-axOAc appeared at  $\tau$  4.46 ( $J_{1,2} = 2.5$  Hz), and that in VIII-eqOAc appeared at 3.93 ( $J_{1,2} = 4.6$  Hz).

## Arylation by Aromatic Nitro Compounds at High Temperatures. II. Nitrobenzene Alone and with Benzene and Benzene-*d*<sub>6</sub>

Ellis K. Fields<sup>1a</sup> and Seymour Meyerson<sup>1b</sup>

*Contribution from the Research and Development Department, Amoco Chemicals Corporation, Whiting, Indiana, and the Research and Development Department, American Oil Company, Whiting, Indiana 46394. Received February 13, 1967*

**Abstract:** The nitroarene bond in nitrobenzene and other aromatic nitro compounds breaks above  $400^\circ$ ; this provides an easy means of generating phenyl and a great many other aromatic radicals. The decomposition of nitrobenzene alone at  $600^\circ$  seems to parallel rather closely its decomposition under electron impact in the mass spectrometer. With benzene and benzene-*d*<sub>6</sub>, nitrobenzene yields mainly biphenyl and terphenyl and their deuterated analogs, respectively. Higher yields than calculated on the basis of only one radical indicate the involvement of the  $\text{NO}_2$  portion of the original nitrobenzene.

Although nitrobenzene has been known for over 130 years<sup>2</sup> and has been the subject of innumerable investigations as well as the source of many useful chemicals, its thermal decomposition products have never been adequately described. Smith<sup>3</sup> studied the kinetics of its decomposition at  $455$ – $515^\circ$  and  $17$ – $92$  min in Pyrex, and concluded that the reaction was largely homogeneous, between first and second order,

with an activation energy of  $51$  kcal/mole. Maksimov<sup>4</sup> determined the first-order rate constant for nitrobenzene decomposition at  $395$ – $445^\circ$ , and confirmed Smith's value for the activation energy. Neither author proposed a mechanism or determined any nongaseous products.

The discovery that the nitroarene bond in nitrobenzene and other aromatic nitro compounds breaks above  $400^\circ$  made possible the easy generation of phenyl and

eat many other aromatic radicals.<sup>6</sup> Our first con- was to determine the scope of this new reaction. ordingly, nitrobenzene was heated in a flow system 00° alone, and in admixture with a wide variety of natic compounds, and the major products were rmined by gas chromatography and mass spec- netry. This paper describes the results of thermal mposition of nitrobenzene alone and with benzene benzene-d<sub>6</sub>.

## Experimental Section

ylations were run in a Vycor tube filled with Vycor beads, in an ric furnace maintained at 600 ± 1° under pure dry nitrogen contact times of 5–20 sec. The vapors were condensed in a at –10°. The condensate was distilled to recover unreacted rial, and the residue was analyzed. Noncondensable gases caught in a gas bulb for analysis.

alyses were performed with a Consolidated Model 21-103c spectrometer with the inlet system at 250 or 325°; with a tly coupled gas chromatograph-mass spectrometer com- ion<sup>4</sup> also employing a 21-103c instrument with an electron iplier in place of the Faraday-cup detector; and by gas chro- graphy on a column of polyethylene glycol sebacate on Chro- rb W. Mass spectra were measured at the conventional 70 ing v and at low voltage, 7.5 v, uncorrected. For the low- ge measurements, the repellers were maintained at an average tial of 3 v, the exact values being selected to give maximum ivity.

reagents and standards for gas chromatography were pur- d from Aldrich Chemicals and used as received. Where y was critical, the reagent was analyzed and, if necessary, ied by distillation, crystallization, and gas chromatography.

a typical experiment, a solution of 5.11 ml (0.05 mole) of benzene in 22.22 ml (0.25 mole) of benzene was passed through cor tube at 600° under nitrogen flowing at 45 cc/min. Contact was 9 sec. The vapors were condensed in a bulb at –10°; ondsensate was distilled to recover 15.3 ml of benzene and give of products, the composition of which is shown in Table III.

## Results and Discussion

itrobenzene Alone. After 20 sec at 600°, nitro- zene was completely decomposed and gave a 30 % yield of the products shown in Table I. To help

The relative intensities of the different species, expressed as fractions of the total ion yield of mass 29 and higher, are shown in Table II. The major single process thus

Table II. Partial Spectrum of Nitrobenzene

Mass	Species	Rel Inten, % <sup>a</sup>	Mass	Species	Rel Inten, % <sup>a</sup>
123	C <sub>6</sub> H <sub>5</sub> NO <sub>2</sub> <sup>+</sup>	11.9	65	C <sub>6</sub> H <sub>5</sub> <sup>+</sup>	3.8
107	C <sub>6</sub> H <sub>5</sub> NO <sup>+</sup>	1.0	51	C <sub>4</sub> H <sub>3</sub> <sup>+</sup>	17.9
93	C <sub>6</sub> H <sub>5</sub> O <sup>+</sup>	3.5	50	C <sub>4</sub> H <sub>2</sub> <sup>+</sup>	7.3
77	C <sub>6</sub> H <sub>5</sub> <sup>+</sup>	28.6	46	NO <sub>2</sub> <sup>+</sup>	0.6
76	C <sub>6</sub> H <sub>4</sub> <sup>+</sup>	1.0	30	NO <sup>+</sup>	4.5

<sup>a</sup> Not corrected for contributions of species containing naturally occurring heavy isotopes.

is loss of NO<sub>2</sub>, directly and to some extent by a two-step sequence, to give C<sub>6</sub>H<sub>5</sub><sup>+</sup>, accompanied by the complementary loss of C<sub>6</sub>H<sub>5</sub> to give NO<sub>2</sub><sup>+</sup>. The C<sub>6</sub>H<sub>5</sub><sup>+</sup> ion splits out acetylene and goes to C<sub>4</sub>H<sub>3</sub><sup>+</sup>. A significant fraction of the nitrobenzene parent ions forms phenoxy ions by loss of NO or NO<sup>+</sup> by loss of a phenoxy radical, presumably through an intermediate nitro-nitrite rearrangement;<sup>7</sup> summing the intensities for C<sub>6</sub>H<sub>5</sub>O<sup>+</sup>, C<sub>6</sub>H<sub>5</sub><sup>+</sup>, C<sub>6</sub>H<sub>4</sub><sup>+</sup>, which most likely arises chiefly by loss of acetylene from C<sub>6</sub>H<sub>5</sub><sup>+</sup>,<sup>8</sup> and NO<sup>+</sup> leads to an estimate of 14.8% for the fraction of nitrobenzene ions that react by this pair of complementary paths.

The thermolysis products can be rationalized in similar fashion. Phenyl radical, formed by breaking of the phenyl-nitro bond, can abstract hydrogen from another molecule of nitrobenzene and give benzene; this is, however, only a minor reaction. It prefers to dimerize to biphenyl or to add to the aromatic system, as in solution chemistry,<sup>9</sup> to give nitrobiphenyls.

At 600° little nitrobiphenyl survives; it undergoes decomposition just as nitrobenzene, and gives biphenyl by hydrogen abstraction, quaterphenyl by dimerization, and hydroxybiphenyl by rearrangement as well as by alkylating the nitrobenzene and nitrobiphenyl.

(8) S. Meyerson, J. D. McCollum, and P. N. Rylander, *ibid.*, **83**, 1401 (1961); S. Meyerson, *ibid.*, **85**, 3340 (1963).

Phenol, and probably some of the hydroxybiphenyl, arises by a nitro-nitrite rearrangement paralleling the process under electron impact.

Dibenzofuran forms from diphenyl ether, *o*-hydroxybiphenyl, or both, by intramolecular loss of hydrogen. It does not come directly from phenol itself, as phenol alone under identical conditions is converted in only 0.5% yield to a mixture of diphenyl ether, hydroxybiphenyls, and dibenzofuran.

The source of quinoline is not apparent. Quinoline results from the reaction of benzyne with pyridine,<sup>10</sup> and benzyne may well form from nitrobenzene at 600° by elimination of HNO<sub>2</sub>, as under electron impact, and indeed may account for all the naphthalene and some of the biphenyl listed in Table I. But whether pyridine forms at all here is uncertain. Intramolecular loss of oxygen at high temperatures has been observed for dibenzothiophene 5,5-dioxide,<sup>11</sup> and could conceivably occur in aromatic nitro compounds to give nitrenes; nitrene precursors form pyridine from benzene by insertion.<sup>12</sup> However, the lack of evidence for both pyridine and phenylpyridines among nitrobenzene decomposition products renders this mechanism unlikely. A 3-carbon atom fragment seems called for, to react with aniline in a Skraup-type synthesis, but none of the other products (except benzo-, dibenzo-, and tribenzoquinolines in trace amounts) gives evidence for such fragments. The formation of quinoline, and the detailed steps in nitrobenzene reduction to aniline, remain to be clarified.

**Nitrobenzene with Benzene and Benzene-*d*<sub>6</sub>.** Nitrobenzene with benzene gave the products shown in Table III. Phenol is a minor product, suggesting that the decomposition of nitrobenzene to phenyl radical and nitrogen dioxide is faster than the nitro-nitrite

Table III. Reaction of Nitrobenzene with Benzene<sup>a</sup>

<sup>a</sup> At 600°, contact time 9 sec. <sup>b</sup> Relative intensities of the parent peaks of components in the mass spectrum measured at reduced ionizing voltage (7.5 v, uncorrected), normalized to biphenyl = 100 and taken as a first approximation to relative concentrations. Sensitivity, *i.e.*, the proportionality factor between parent-peak intensity and concentration, differs from one compound to another. However, closely related compounds have roughly equal sensitivities at the ionizing voltage employed in our work [G. F. Crable, G. L. Kearns, and M. S. Norris, *Anal. Chem.*, **32**, 13 (1960)]. For example, in the same sample analyzed by both low-voltage mass spectrometry and gas chromatography, the ratios of the concentrations of phenol and biphenyl were 1.37 and 1.35, respectively. In any case, the use of relative intensities is perfectly valid for intercomparison of concentration ratios of identical components in separate samples [S. Meyerson and E. K. Fields, *Chem. Commun.*, 275 (1966)] within the limits of reproducibility of the low-voltage data.

rearrangement. Most of the biphenyl arises by reaction of benzene with the nitrobenzene rather than dimerization of the phenyl radical from nitrobenzene decomposition, as shown by the increasing proportion of biphenyl with decreasing concentration of the nitrobenzene. The yields of products are considerably different in the reactions at the two different concentration ratios, and thus give a clue to the mechanism of biphenyl formation.

At a nitrobenzene:benzene mole ratio of 1:5, the yield of biphenyl and terphenyl combined, as measured by gas chromatography, was 85 mole % based on 1 mole of phenyl radical produced per mole of nitrobenzene decomposed. At a mole ratio of 1:25, the yield on the same basis jumped to 170%. Both the phenyl radical and the nitrogen dioxide from the nitrobenzene must have been involved. The sequence of reactions is probably

Benzene in nitrogen dioxide at 600° gave a 12% yield of biphenyl plus terphenyl.

The gases from the reaction of nitrobenzene with benzene at 1:5 mole ratio at 600° run under helium

At 600°, contact time 9.3 sec; mole ratio nitrobenzene:benzene = 1:5; isotopic composition of benzene, 0.2%  $d_4$ , 5.7%  $d_5$ , %  $d_6$ . <sup>b</sup> Estimated from low-voltage (7.5 ionizing v, uncorrected) mass spectrum. <sup>c</sup> Relative intensities in the low-voltage spectrum, normalized to benzene = 100.

the percentage composition:<sup>13</sup> CO<sub>2</sub>, 0.3; CO, N<sub>2</sub>O, 0.9; NO, 9.8; N<sub>2</sub>, 0.7; H<sub>2</sub>, 1.4; He, 84.5. NO<sub>2</sub> fragment of the nitrobenzene molecule apparently ends up chiefly as nitric oxide, either by direct action or *via* a series of free radical hydrogen abstractions and decompositions.<sup>14</sup>

to observe more clearly the interaction of nitrobenzene fragments, nitrobenzene was decomposed at 600° in benzene- $d_6$  and the isotopic distribution of the products determined, as shown in Table IV. Despite the inevitable scrambling of protium and deuterium,<sup>15,16</sup> the results are revealing.

<sup>i</sup>) Small amounts of NO<sub>2</sub> might have been present and been removed by inadvertent chemical reaction with surface deposits in the massrometer. See R. A. Friedel, A. G. Sharkey, J. L. Shultz, and C. R. Bert, *Anal. Chem.*, 25, 1314 (1953).

<sup>j</sup>) For the structure of nitrous acid in the gas phase and its dissociation products, see A. P. Cox and R. L. Kuczkowski, *J. Am. Chem. Soc.*, 88, 7071 (1966), and references cited therein.

Biphenyl consisted mainly of four species:  $d_5$ ,  $d_6$ ,  $d_9$ , and  $d_{10}$ . Only 0.7% was unlabeled; this measures roughly the extent of dimerization of the phenyl radical derived from nitrobenzene. Almost 40 times as much was biphenyl- $d_{10}$ , formed presumably by abstraction of a deuterium atom from the benzene- $d_6$  by either fragmentation of the decomposed nitrobenzene, followed by dimerization of the phenyl- $d_5$  radical or arylation of benzene- $d_6$  by the phenyl- $d_5$  radical. The appreciable amount of biphenyl- $d_6$  probably forms in part, at least, by arylation of benzene- $d_6$  by the phenyl- $d_5$  radical. Arylation of benzene- $d_6$  by unlabeled phenyl radical should give biphenyl- $d_5$ ; the formation of almost as much biphenyl- $d_6$  suggests that in the reaction

the intermediate phenylcyclohexadienyl radical has a lifetime sufficiently long to exchange protium and deuterium intramolecularly before it is restored to full aromaticity. This is perhaps not too surprising, in view of the evidence for a phenylcyclohexadienyl intermediate in scrambling of protium and deuterium in the pyrolysis of benzene- $d_6$ .<sup>15a</sup>

Isotopic composition of the terphenyl indicates that the bulk of the terphenyl consists of two rings originally derived from benzene- $d_6$  and one from nitrobenzene. This suggests either of two processes: phenylation of biphenyl- $d_5$  and - $d_{10}$  by unlabeled phenyl radical, or attack by phenylcyclohexadienyl radical on benzene- $d_6$ , followed by rearomatization. That the concentration of terphenyl- $d_4$  is less than half that of terphenyl- $d_5$ , if these small numbers are significant, may be accounted for by an isotope effect, directing the incoming phenyl radical to the unlabeled, rather than to the deuterated, benzene ring.

Isotopic composition of the phenol is unexpected. Such a reactive aromatic system should exchange ring hydrogens with benzene- $d_6$  more readily than an unsubstituted benzene, which from the isotopic spread seems to be the case. However, phenol- $d$  would be predicted far to exceed in amount the unlabeled phenol, if abstraction by the phenoxy radical occurred with equal ease from benzene- $d_6$  or nitrobenzene. Formation of more unlabeled than monodeuterated phenol suggests a reaction involving an intermediate derived from two molecules of nitrobenzene, in which the phenoxy radical site has ready access to a source of hydrogen.

(15) (a) E. K. Fields and S. Meyerson, *ibid.*, 88, 21 (1966); (b) *ibid.*, 88, 3388 (1966).

(16) To estimate the extent of scrambling to be expected, an equimolar mixture of benzene and benzene- $d_6$  was heated at 600° for 9 sec. The percentage isotopic composition of the recovered benzene was:  $d_0$ , 46.2;  $d_1$ , 4.0;  $d_2$ , 0.4;  $d_3$ , 0.1;  $d_4$ , 0.7;  $d_5$ , 6.8;  $d_6$ , 41.8. The scrambling is low enough to justify conclusions drawn from the reaction of nitrobenzene with benzene- $d_6$ .

Subsequent articles will describe the phenylation of additional aromatic and heterocyclic compounds by nitrobenzene at elevated temperatures.

## The Participation of Solvent and General Acids in Acetal Hydrolysis. The Hydrolysis of 2-(*para*-Substituted Phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes

Thomas H. Fife

*Contribution from the Department of Biochemistry, University of Southern California, Los Angeles, California 90033. Received January 20, 1967*

**Abstract:** The hydrolysis of 2-phenyl-4,4,5,5-tetramethyl-1,3-dioxolane in 0.100 *M* HCl is characterized by a  $\Delta S^\ddagger$  of  $-14.2$  eu and a  $D_2O$  solvent isotope effect of  $k_D/k_H = 2.4$ . The value of  $\rho$  for hydrolysis of a series of 2-(*para*-substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes in 0.100 *M* HCl at  $30^\circ$  was found to be  $-2.0$ . The values of  $\Delta S^\ddagger$  and  $k_D/k_H$  are considerably less than normally found in acetal hydrolysis while the  $\rho$  value is much more positive than found previously for hydrolysis of the diethyl acetals of *meta*- and *para*-substituted benzaldehydes. The rate constants for hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane in moderately concentrated HCl solutions are proportional to the stoichiometric acid concentration while a plot of  $\log k_{\text{obsd}}$  vs.  $-H_0$  shows a pronounced downward curvature. The slope  $w$  of a plot of  $\log k_{\text{obsd}} + H_0$  vs. the logarithms of the activity of water is  $+1.9$ . Thus the evidence supports the incursion of an A2 mechanism involving attack of water on the protonated substrate. The rate of hydrolysis of 2-(*p*-methoxyphenyl)-4,4,5,5-tetramethyl-1,3-dioxolane is subject to catalysis by increasing concentrations of formic acid at constant pH and ionic strength.

The generally accepted mechanism for the acid-catalyzed hydrolysis of acetals involves a fast pre-equilibrium protonation of the substrate followed by a unimolecular rate-determining decomposition to an alcohol and a resonance-stabilized carbonium ion.<sup>1</sup> The hydrolysis of fully protonated 2-(substituted phenyl)-3-ethyloxazolidines, carbonyl derivatives similar to acetals (1,3-dioxolanes) in which an oxygen has been replaced by an N-ethyl group, is marked however by solvent participation and general catalysis in the ring-opening step.<sup>2</sup>

It was thought that similar mechanisms might be observable in the hydrolysis of acetals if the A1 transition state could be made sterically unfavorable. Intramolecular participation by various functional groups in acetal hydrolysis has been postulated in several instances.<sup>3-6</sup> The mechanism of such participation, however, has not been established. The clearly unambiguous finding of buffer catalysis and solvent participation in an acetal hydrolysis could lead to insight into the mechanistic possibilities by which glycosidic enzymes effect catalysis since it is likely that functional groups at the active sites of these enzymes are involved in the bond-breaking process.

In preliminary work it was found that the hydronium ion catalyzed hydrolysis of 2-(*p*-methoxyphenyl)-4,4,5,5-tetramethyl-1,3-dioxolane proceeded in water at  $30^\circ$  with a second-order rate constant approximately

1030-fold less than that of the corresponding ethylene glycol derivative. There is little doubt that this large observed effect is steric in origin resulting from substitution at the 4 and 5 positions in the 1,3-dioxolane ring system. While this rate effect could be reflecting differences in the dissociation constants for the conjugate acids it is also quite likely that the bond-breaking process is strongly hindered with the tetramethylethylene glycol derivative due to greater steric interactions in the A1 transition state than in the ground state. Since the 1,3-dioxolane ring is normally puckered by carbon-oxygen bond angles of less than  $109^\circ$ ,<sup>7</sup> a substantial dihedral angle should exist between the methyl groups on adjoining carbons so that ground-state interactions would not be unusually large. A detailed study of the hydrolysis of a series of 2-(substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes has therefore been made. It has indeed been found that the hydrolysis reactions of these acetals proceed by an A2 mechanism with general acid catalysis by formic acid being detectable.

### Experimental Section

**Materials.** 2-(*para*-Substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes were prepared by refluxing in benzene or toluene equivalent amounts of the appropriately substituted benzaldehyde and tetramethylethylene glycol. A trace of *p*-toluenesulfonic acid was added as a catalyst. Water was continuously removed from the reaction by azeotropic distillation with the solvent. After collection of a theoretical amount of water the reaction mixture was washed with 1 *M* KOH solution. The benzene or toluene extract was then dried over anhydrous sodium sulfate. The solvent was removed by flash evaporation, and the residue was either distilled or recrystallized from an ether-hexane mixture.

Dioxane was purified by the method of Fife<sup>9</sup> and was stored frozen.

**Kinetic Measurements.** The rates of appearance of the aldehyde products in water as the solvent were measured spectrophotometrically with a Zeiss PMQ 11 spectrophotometer. The dioxolane, dissolved in dioxane, was added to the aqueous solution in a thermostated cuvette in the cell compartment of the spectrophotometer by means of a calibrated dropping pipet. The solution was then stirred vigorously. The rates were generally followed to 75–90% completion, and infinity points were taken at 10–20 half-lives. Pseudo-first-order rate constants ( $k_{\text{obsd}}$ ) were obtained from the slopes of plots of  $\log (OD_{\infty} - OD_t)/(OD_{\infty} - OD_0)$  vs. time. Constant temperature ( $\pm 0.1^\circ$ ) was maintained in kinetic runs by circulating water from a Haake Model F constant-temperature circulating bath through a Zeiss constant-temperature cell holder. All pH measurements were made with a Radiometer pHM 22 pH meter.

In all work utilizing 99.8%  $D_2O$  as the solvent, the glass electrode correction formula of Fife and Bruce<sup>9</sup> was employed in the determination of  $a_D^+$ .

The determination of activation parameters for hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane in 0.100 M HCl points obtained at four temperatures (20, 30, 40, and 50°)  $\pm 0.1^\circ$ . Rates were measured in triplicate at each temperature with an average deviation of less than 2% in the rate constants in all cases.

## Results

The rate constants for hydrolysis of the series of 2-(*para*-substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes in 0.100 M HCl at 30° are presented in Table I.

Figure 2 is shown a plot of the logarithms of these rate constants vs.  $1/T^\circ K$ . The value obtained for  $\Delta H^\ddagger$  is  $16.1 \pm 0.5$  kcal/mole and  $\Delta S^\ddagger$  has the value  $-14.2 \pm 1.7$  eu calculated at 30° with the rate constant having the units l. mole<sup>-1</sup> sec<sup>-1</sup>. The errors reported in  $\Delta H^\ddagger$  and  $\Delta S^\ddagger$  were calculated from the standard error of the regression coefficient of a plot of  $\ln k_{\text{obsd}}$  vs.  $1/T^\circ K$ .

The hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane was studied as a function of increasing concentrations of HCl. The rate constants are reported in Table III. It can be seen in Figure 3

Figure 3. Plot of  $\log k_{\text{obsd}}$  for hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane at 30° vs. the logarithms of HCl concentration ( $\log C_{\text{H}_3\text{O}^+}$ ),  $\circ$ , or  $-H_0$ ,  $\ominus$ .

Figure 4. Plot of  $\log k_{\text{obsd}} + H_0$  for hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane at 30° vs. the logarithms of the activity of water.

that the logarithms of the rate constants are proportional to the logarithms of the stoichiometric acid concentration while curvature is obtained in a plot vs.  $-H_0$ . It will be noted, however, that the slope of the plot of  $\log k_{\text{obsd}}$  vs.  $\log C_{\text{H}_3\text{O}^+}$  is 2.0 rather than 1.0 as might be expected. In Figure 4 is presented a plot of  $\log k_{\text{obsd}} + H_0$  vs. the logarithms of the activity of water in these solutions.<sup>11</sup> A straight line through these points has a slope,  $w$ ,<sup>11</sup> of +1.9.

The rate of hydrolysis of 2-(*p*-methoxyphenyl)-4,4,5,5-tetramethyl-1,3-dioxolane was found to be catalyzed by increasing concentrations of formate buffer at 40°. The observed catalysis is weak, but it is well outside the range of possible experimental error. The observed rate constants obtained at two pH values are plotted in Figure 5 vs. total formate concentration ( $\text{HCOOH} + \text{HCOO}^-$ ). The slopes of the lines increase as pH is decreased showing a kinetic dependence upon the concentration of the acid species. The rate constant for the general acid catalyzed reaction is  $0.0026 \text{ l. mole}^{-1} \text{ min}^{-1}$ .

## Discussion

Mechanisms designated A2 involving attack of solvent on the protonated substrate have been postulated in the hydrolysis of several different types of acetals.<sup>5,12,13</sup> In none of these cases, however, was more

Figure 5. Plot of  $(k_{\text{obsd}} - k_0)$  for hydrolysis of 2-(*p*-methoxyphenyl)-4,4,5,5-tetramethyl-1,3-dioxolane vs. total formate concentration ( $\text{HCOOH} + \text{HCOO}^-$ ) at 40° and  $\mu = 0.5 \text{ M}$ . The values of the intercept rate constants,  $k_0$ , are  $0.00407 \text{ min}^{-1}$  at pH 3.54 and  $0.0010 \text{ min}^{-1}$  at pH 4.16.

than one criteria of mechanism applied, and in each case some doubt exists as to the correctness of the assigned mechanism. Thus Kreevoy and Taft<sup>14</sup> have pointed out that the data of Kaeding and Andrews<sup>12</sup> on the hydrolysis of the diethyl ketal of *p*-nitrobenzophenone in ethanol-water mixtures is also compatible with an A1 mechanism. Kwart and Price<sup>13</sup> suggested that the hydrolysis of 2,2-diphenyl-1,3-dioxolane was A1, and a series of similar 2,2-disubstituted 1,3-dioxolanes all have  $\text{D}_2\text{O}$  solvent isotope effects characteristic of an A1 mechanism.<sup>15</sup> Capon and Thacker<sup>6</sup> postulated on the basis of slightly negative values of  $\Delta S^\ddagger$  that furanoside hydrolysis has an A2 mechanism, but it has been found that the hydrolysis of 2-ethoxytetrahydrofuran, a model furanoside, is characterized by a  $\Delta S^\ddagger$  of +3.3 eu<sup>16</sup> which although considerably more negative than that for hydrolysis of 2-ethoxytetrahydropyran is still in the range normally associated with an A1 mechanism.<sup>17</sup> In addition, a  $\text{D}_2\text{O}$  solvent isotope effect characteristic of an A1 reaction was found.<sup>16</sup>

In the present study several mechanistic criteria have been applied to the hydrolysis of 2-(substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes and some point strongly to incursion of an A2 mechanism in the hydrolysis of these compounds. A ratio of  $k_{\text{D}}/k_{\text{H}}$  of 2.4 was found for the hydrolysis of 2-phenyl-4,4,5,5-tetramethyl-1,3-dioxolane. Ratios of  $k_{\text{D}}/k_{\text{H}}$  in the range 1.3–1.7 are normally associated with A2 reactions while ratios greater than this can be considered as indicative of an A1 mechanism.<sup>18</sup> The  $\text{D}_2\text{O}$  solvent isotope effects found in A1 acetal hydrolysis reactions vary generally from approximately 2.7 to 3.0.<sup>1,15</sup> Thus the value of  $k_{\text{D}}/k_{\text{H}}$  of 2.4 found in the present study is considerably less than is usually found for A1 acetal hydrolysis.

The value of  $\Delta S^\ddagger$  for hydrolysis of 2-phenyl-4,4,5,5-tetramethyl-1,3-dioxolane,  $-14.2 \text{ eu}$ , is not as highly

negative as one might expect to find in an A2 reaction where values in excess of  $-15$  eu are commonly observed<sup>17</sup> but is still more in accord with a mechanism involving solvent participation than with a unimolecular mechanism. The A1 cleavage of the 1,3-dioxolane ring system is characterized by  $\Delta S^\ddagger$  values  $8$ – $10$  eu more negative than for hydrolysis of the analogous open-chain diethyl acetals,<sup>1,15</sup> but the  $\Delta S^\ddagger$  for hydrolysis of 2-phenyl-1,3-dioxolane in 50% dioxane–H<sub>2</sub>O is still only  $-8.9$  eu,<sup>1</sup> so the value observed in the case of tetramethylethylene glycol acetal is much more negative.

The logarithms of the rate constants for hydrolysis of the series of 2-(substituted phenyl)-4,4,5,5-tetramethyl-1,3-dioxolanes are a linear function of  $\sigma$  with a  $\rho$  of  $-2.0$  in contrast to the upward curvature obtained in the plot of  $\log k_H$  for hydrolysis of the diethyl acetals and ethylene glycol acetals of substituted benzaldehydes vs.  $\sigma$ .<sup>1</sup> Employing *meta*-substituted benzaldehyde diethyl acetals  $\rho$  was found to be  $-3.35$ ,<sup>1</sup> so the value obtained in the present study is much more positive. Electron withdrawal should hinder protonation, make departure of the leaving group more difficult, and destabilize a carbonium ion intermediate in an A1 reaction. Nucleophilic attack by solvent, however, should be facilitated by electron withdrawal. Solvent participation therefore should result in a less negative value of  $\rho$ . The linear relationship with  $\sigma$  shows there to be much less carbonium ion character in the transition state for hydrolysis of the tetramethylethylene glycol acetals than in the case of the diethyl acetals or ethylene glycol acetals since it is undoubtedly resonance interaction of the *p*-methoxy group with the incipient carbonium ion in the transition state that causes positive deviation in the latter series of compounds.

A classic method for distinguishing between A1 and A2 mechanisms has been to determine whether the observed rate constants are proportional to the stoichiometric acid concentration or to  $h_0$ .<sup>19</sup> Bearing in mind the criticisms that have been made of this method and the possible exceptions that have been found,<sup>20</sup> the linear relationship between  $\log k_{\text{obsd}}$  and  $\log$  acid concentration  $C_{\text{H}_3\text{O}^+}$  would strongly suggest an A2 mechanism for the hydrolysis of 2-(*p*-nitrophenyl)-4,4,5,5-tetramethyl-1,3-dioxolane. The  $w$  value of  $+1.9$  is also in the range associated with solvent participation in the Bunnett classification,<sup>11</sup> water acting as a nucleophile. This  $w$  value is, of course, only approximate because of the scatter of points about the line in Figure 4, but there is no question that the slope is quite positive for hydrolysis in the more concentrated acid solutions. The positive value of  $w$  can be contrasted with the highly negative values that are generally observed for acetal hydrolysis.<sup>11</sup>

A complication in the interpretation of the data obtained in moderately concentrated HCl is the high slope of 2.0 found in the plot of  $\log k_{\text{obsd}}$  vs.  $\log C_{\text{H}_3\text{O}^+}$ . Slopes considerably greater than unity have been observed in plots of  $\log k$  vs.  $-H_0$  for acetal hydrolysis in HCl solutions although such plots are linear.<sup>14,21</sup> Possible explanations for this behavior are salt effects on the activity coefficients<sup>19,22</sup> or nucleophilic participation by chloride ion.<sup>11</sup> The best straight line through the present  $H_0$  plot has a slope of 0.84.

Each piece of evidence cited in the present study contains some ambiguity, but taken together a consistent picture is presented of a reaction in which water is participating as a nucleophile but in which either the bond being formed in the transition state is not well developed or in which an A1 mechanism is still making

some contribution to the observed rate.

If water can participate in the reaction it is reasonable that buffer catalysis might also be observed. The catalysis observed in formate buffer (Figure 5) is small but certainly real. This then is the first reported example of buffer participation in acetal hydrolysis. No rate enhancements were observed for hydrolysis of benzaldehyde diethyl acetal in the same series of buffers at 25°. Thus the observed catalysis is very likely not due to medium effects caused by increasing buffer concentrations.

The different mechanisms observed in the present study can be seen because the normally favored A1 mechanism has been made unfavorable by the increased steric bulk. The rates of hydrolysis of the tetramethylethylene glycol acetals are many times slower than those of the corresponding ethylene glycol acetals even though solvent and buffer are involved. It would appear, however, that glycosidic enzymes probably function by extremely facile general acid–general base mechanisms in which the participating groups catalyze the reactions near neutrality at rates much greater than can be observed in simple acid-catalyzed reactions at the same pH values. Before mechanisms of this type can be understood it must, of course, be demonstrated that they are indeed chemically feasible, and the structural features which promote their utilization must be determined. A step in that direction has now been taken.

# High-Resolution Mass Spectrometry in Molecular Structure Studies. IV. Mechanistic Aspects of the Fragmentation of Widdrol<sup>1,2</sup>

A. L. Burlingame, Catherine Fenselau,<sup>3a</sup> and W. J. Richter<sup>3b</sup>

Contribution from the Department of Chemistry and the Space Sciences Laboratory, University of California, Berkeley, California 94720. Received January 11, 1967

**Abstract:** The mass spectrum of the sesquiterpenol widdrol is dominated by the peak at  $m/e$  151, corresponding to the charged species formed by loss of 71 mass units from the molecular ion. The mass spectra of a series of deuterium-labeled analogs and the complete high-resolution mass spectrum indicate that most of the  $M - 71$  ions arise from a rearranged molecular ion, rather than from that of the original alicyclic alcohol. The presence of homoallylic unsaturation allows postulation of extensive rearrangement to a ketonic molecular ion.

In spite of their broad occurrence in nature, their chemical and biogenetic importance, their volatility, and the ample functional variation of basic skeletal moieties in this class of natural products, the sesquiterpenes and also diterpenes have received little attention in the mass spectrometry literature thus far. A few complete low-resolution mass spectra and comparatively little mechanistic work toward their interpretation have been reported,<sup>4</sup> although the low-resolution mass spectrum of widdrol (Figure 1) and a suggestion for the composition and the origin of the dominating fragment<sup>5</sup> are among them.

This situation is clearly a result of the usual difficulties experienced in interpreting spectra of alicyclic compounds, even those of quite simple structure, without having at hand the necessary high-resolution data and supplemental information from labeled analogs. The demand for utilization of high-resolution techniques plus proper deuterium labeling as minimum requirements in the case of monoterpenes has only recently been emphasized by several authors.<sup>6</sup> Complete high-resolution mass spectra of the sesquiterpene lactone gaillardin and its derivatives have recently been presented by this laboratory in support of its structural elucidation.<sup>7</sup>

The structure and absolute configuration of widdrol (I) were established after extensive discussion in 1961.<sup>8</sup>

Subsequently, in 1964, Dauben and Friedrich<sup>9</sup> elucidated the mechanism of conversion of thujopsene to widdrol in aqueous acidic media, the analogs 6,6- $d_2$ -widdrol (III) (Figure 3) and 8,8- $d_2$ -widdrol (IV) (Figure 4) being of primary importance in that context. The availability of these labeled compounds and that of widdrol-OD (II) (Figure 2) led to this mass spectral examination of the major modes of decomposition for this naturally occurring sesquiterpenol. Complete high-resolution data were determined for these compounds and presented in the format of heteroatomic plots<sup>9</sup> for ease of evaluation of labeling data.

## The Fragmentation of Widdrol

If widdrol is viewed as a cyclic alcohol, it would be expected to undergo the characteristic fragmentation outlined for alicyclic alcohols by Natalis<sup>10</sup> and substantiated by use of deuterium-labeled analogs for cyclopentanol<sup>11</sup> and cyclohexanol.<sup>12</sup> Thus, the molecular ion  $M_0$  should suffer allylic bond scission  $\alpha$  to the hydroxyl group, followed by transfer of an  $\alpha$ -hydrogen and cleavage of the  $\beta, \gamma$  bond.

That this fragmentation sequence yielding ion a does occur to a certain extent is borne out by the high-resolution mass spectrum of widdrol (Figure 5), which shows that virtually all of the peak at  $m/e$  71 arises from ions having the composition  $C_4H_7O$ . In the spectrum of 8,8- $d_2$ -widdrol (IV) (Figure 4), most of the peak appears at  $m/e$  72,<sup>13</sup> the corresponding ion retaining only one deuterium atom as expected. Similarly, in the low-resolution mass spectrum of widdrol-OD (II) (Figure

(13) All intensities of peaks discussed are corrected for isotopic purity.

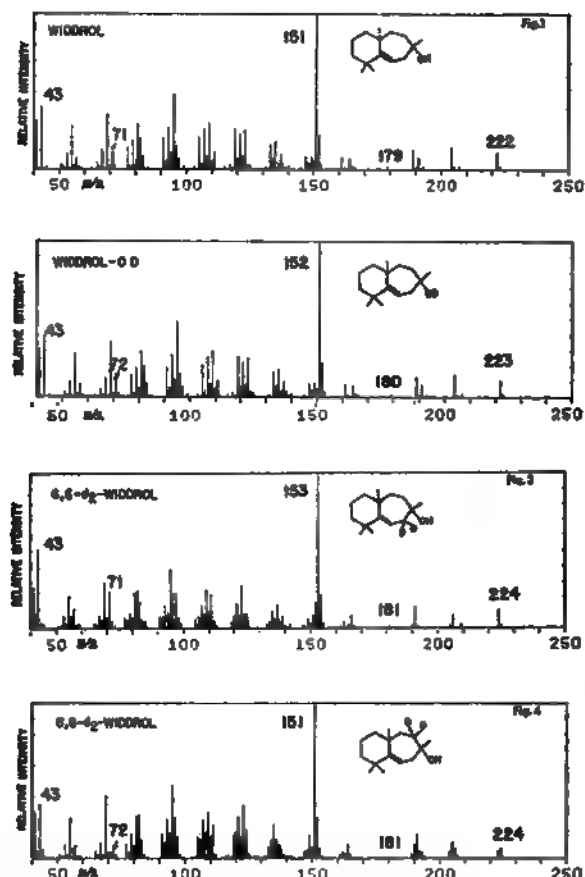

Figure 1. Mass spectrum of widdrol (I).

Figure 2. Mass spectrum of widdrol-OD (II).

Figure 3. Mass spectrum of 6,6-*d*<sub>2</sub>-widdrol (III).Figure 4. Mass spectrum of 8,8-*d*<sub>2</sub>-widdrol (IV).

2), at least 70% of the peak at  $m/e$  71 is shifted to  $m/e$  72 owing to predominant retention of the hydroxyl hydrogen atom.<sup>13</sup>

It should be noted, in addition, that some of the charge seems to be transferred to the hydrocarbon moiety in the final step of this fragmentation sequence, leading to ion b. The precursor ion for both modes of final cleavage, namely, the rearranged molecular ion  $M_2$ , can be viewed as a "new" enolic molecular ion.

Figure 5. High resolution mass spectrum of widdrol (I).

Such heterolytic cleavage of the 9,9a bond accounts for only a minor portion of the total ion current at  $m/e$  151. Support for a second process contributing to the  $C_{11}H_{19}$  ions is shown by noting that (a) 15% of the original peak intensity remains at  $m/e$  151 in widdrol-OD, and (b) a comparable fraction of the  $C_{11}H_{19}$  ions shifts to  $m/e$  152 in 8,8-*d*<sub>2</sub>-widdrol (Figure 4).

As evident from the shift of the major part of the peak at  $m/e$  151 to 152 in the spectrum of compound II (Figure 2), another and much more important mode of fragmentation of the skeleton must be operative in addition to that leading to ion b. The sequence of processes involved seems to be triggered by the presence of the homoallylic bond, since there is no evidence for an analogous sequence in the fragmentation of saturated alicyclic alcohols.

The interpretation presented for the genesis of this main component of the  $C_{11}H_{19}$  ion current includes again as the initial step a rearrangement of the original molecular ion  $M_0$  to an "open" isomeric species  $M_2$ , which represents a "ketonic" ion in contrast to the "enolic" ion  $M_1$ . Several mechanistic pathways may be postulated for this rearrangement. One mechanistic possibility ( $M_0 \rightarrow M_2$ ) would depict transfer of the hydroxyl hydrogen to the double bond in  $M_0$  via a six-membered transition state with rupture of the B ring resulting in the generation of a "methyl ketonic" molecular ion,  $M_2$ .

Such a hydrogen transfer with double-bond migration can be regarded as a cyclic analog of the frequently observed McLafferty rearrangement of open-chain olefins or carbonyl compounds containing  $\gamma$ -hydrogen atoms attached to carbon. Djerassi, *et al.*,<sup>14</sup> have suggested from their work on McLafferty rearrangements in steroidal ketones a 1.8-Å maximum allowable distance

(14) C. Djerassi and L. Tokes, *J. Am. Chem. Soc.*, **88**, 536 (1966), and references therein.

between carbonyl oxygen and the hydrogen atom transferred. Although the steroid model is not strictly analogous, a comfortable conformation of the atoms concerned within 1.8 Å is easily possible for widdrol, as estimated from Dreiding models.

A mechanistic alternative involves initial  $\alpha$ -allylic cleavage with subsequent abstraction of the hydroxyl hydrogen *via* a seven- or nine-membered transition state. Again, an open ketonic molecular ion, *e.g.*,  $M_3$  or  $M_4$ , would result. That a predominant prefer-

ence exists in the case of  $M_1$  for the abstraction of the hydroxyl hydrogen rather than the activated  $\alpha$ -hydrogens, as is the dominant process in the alicyclic alcohol model,<sup>10-12</sup> would not be expected, and the driving force is unclear. Of course, generation of an allylically stabilized radical leads to a less reactive radical site and, as a consequence, higher selectivity rendering preferred abstraction from conformationally less but energetically more favorable sites could result. In contrast to the foregoing discussion, conceptual preference for the hydroxyl hydrogen over that of C-7 methyl hydrogens utilizing a McLafferty-type mechanism is reasonable.

Assuming the formation of such a rearranged molecular ionic species, *e.g.*,  $M_3$  or  $M_4$ , its subsequent modes of fragmentation will then be governed by its methyl ketonic nature.  $\alpha$  Cleavage produces ion *c* ( $C_2H_5O$ ), as expected, from a methyl ketone, which accounts for nearly all of the abundant peak at  $m/e$  43. The corresponding  $C_2H_5O$  ions formed from the three labeled derivatives contain no deuterium atoms. A minor portion of the charge is carried by the complementary fragment *d* ( $m/e$  179). This hydrocarbon fragment acquires one deuterium atom in the spectrum of widdrol-OD (Figure 2), two deuterium atoms in 6,6- $d_2$ -widdrol (Figure 3), and also two atoms in 8,8- $d_2$ -widdrol (Figure 4).<sup>13</sup> The classical McLafferty ketone rearrangement of  $M_3$  or  $M_4$  is *a priori* inhibited since the position  $\gamma$  to the carbonyl function is quaternary. A datum from the literature<sup>15</sup> reveals that the major contribution to the total ionization of a model  $\gamma$ -quaternary ketone, *cf.* 2,2,8,8-tetramethylnonan-5-one (V), is borne by the quaternary hydrocarbon moiety upon cleavage of the  $\beta,\gamma$  bond.

(15) R. Arndt and C. Djerassi, *Chem. Commun.*, 578 (1965).

Formally, this is the exact mechanistic model which is invoked to explain the major contribution to the peak at nominal  $m/e$  151, which dominates the fragmentation pattern of widdrol  $M_3$  or  $M_4 \rightarrow e$ .

Data from the deuterium-labeled derivatives quantitatively support this discussion, *e.g.*, (a) in widdrol-OD (Figure 2), 85%<sup>13</sup> of the peak at  $m/e$  151 shifts to  $m/e$  152; (b) in 6,6- $d_2$ -widdrol (Figure 3), an even more significant portion shifts to  $m/e$  153; and (c) in 8,8- $d_2$ -widdrol (Figure 4), the peak at  $m/e$  151 remains unshifted, since C-8 and attached deuterium atoms are eliminated in the fragmentation.

This second phase of the fragmentation of the original molecular ion, namely, the final decomposition of the rearranged "ketonic" species to the fragment of mass 151, may, as formulated, proceed *via* a direct cleavage as a one-step process or may comprise a sequence of several steps. Considering the latter case, a sequential loss of methyl radical, carbon monoxide, and ethylene from any of the ketonic intermediates would give ion *e* as well.

There are, however, no metastable peaks in the spectrum of widdrol permitting a decision between these two alternatives. The model ketone V does exhibit a metastable peak for the second step, namely, the loss of carbon monoxide from the acylium ion.<sup>16</sup> The  $M - 15$  and  $M - 43$  peaks, *e.g.*,  $m/e$  207 and 179, respectively, in the spectrum of widdrol could be interpreted as being intermediates of such a sequential fragmentation.

Several ions of abundance comparable to that of the molecular ion can be defined with regard to their structural origin. The first ion (f) occurring at  $m/e$  164 ( $M - 58$ ,  $C_{12}H_{20}$ ) in the natural product shifts unexpectedly to  $m/e$  165 in widdrol-OD and to  $m/e$  166 in 6,6- $d_2$ -widdrol and remains unshifted in 8,8- $d_2$ -widdrol. Since the hydroxyl hydrogen is retained in the fragment under discussion, one is required to postulate the occurrence of a "reciprocal" double hydrogen transfer during the lifetime of the molecular ion. This behavior is analogous to that of ion *e* and would suggest, therefore,

(16) Professor C. Djerassi, Stanford University, private communication.

common mechanistic genesis. The neutral species generated is of composition  $C_2H_6O$  and would be consistent with loss of a molecule of acetone from ions of  $M_4$ . Positional origin for the hydrogen transferred back to the carbonyl group cannot be deduced from these data, but it is assumed that a five- or seven-membered transition state is involved.

Thus, fragmentation can be distinguished in the mass spectrum of widdrol from "alcohol" as well as "ketone" molecular ions, which both produce daughter ions of the same exact mass in their major fragmentation patterns. In one case, the hydroxyl hydrogen is transferred, and the charge remains primarily on the hydroxyl moiety. In the other, a ring hydrogen is transferred, and most of the charge remains on the ring-containing fragment. Such rearrangement of molecular ionic species prior to fragmentation is not unique to the  $\beta,\gamma$ -unsaturated alcohol, widdrol.<sup>17</sup> Similar observations and suggestions have been recorded in at least six earlier papers, e.g., on 2-phenyl-1-propanol<sup>18</sup> and derivatives,<sup>19</sup> on derivatives of 3-buten-2-ol,<sup>20</sup> on  $\beta$ -hydroxy esters,<sup>21</sup> on several hydroxy ketones,<sup>22</sup> and on 19-hydroxy steroids.<sup>23</sup> The thermal

The high-resolution spectra of isopulegol, terpen-4-ol, and their analogs obtained in this laboratory indicate that these homoallylic alcohols also rearrange to carbonyl ions under electron impact.

equivalent of such a rearrangement is known as well, e.g., in  $\beta$ -hydroxy olefins<sup>24</sup> and  $\beta$ -hydroxy esters.<sup>21</sup>

## Experimental Section

Widdrol-OD (II) was obtained by exchanging a sample of widdrol on a  $D_2O$ -treated vpc column<sup>25</sup> and co-inserting it into the mass spectrometer with a microliter of heavy water. Its isotopic purity was calculated from the spectrum to be 83%  $d_1$  and 17%  $d_2$ . The isotopic purity of 6,6- $d_2$ -widdrol was determined as 93%  $d_1$  and 7%  $d_2$ , and that of 8,8- $d_2$ -widdrol as 43%  $d_1$  and 43%  $d_2$ .

The low-resolution mass spectra of widdrol, widdrol-OD, 6,6- $d_2$ -widdrol, and 8,8- $d_2$ -widdrol were obtained on a modified<sup>26</sup> CEC 21-103C mass spectrometer (inlet system 100°, ion source 180°, ionizing energy 70 eV). The high-resolution mass spectrum of widdrol was obtained on a CEC 21-110B mass spectrometer operating with the inlet system at 180° and the ion source at 200°. In the spectra presented (Figure 5), the masses are plotted in methylene units.<sup>9</sup> On the abscissa, each major division marker corresponds to the saturated ion, e.g.,  $C_nH_{2n+1}$ , with the number of carbon atoms given in the top row of figures and the number of hydrogen atoms indicated in the bottom row. There are 14 units between each major division, and the number of hydrogen atoms of an unsaturated or cyclic ion is obtained simply by determining the difference from the position of the next higher saturated ion.

**Acknowledgment.** The authors are indebted to Professor W. G. Dauben for kindly providing the deuterated widdrol analogs II and III and to L. E. Friedrich for valuable discussions.

## Structures of the Indole Alkaloids Kopsingine and Kopsaporine

David W. Thomas,<sup>1a</sup> K. Blemann,<sup>1a</sup> A. K. Kiang,<sup>1b</sup> and R. D. Amarasingham<sup>1b</sup>

Contribution from the Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Massachusetts, and from the Department of Chemistry, University of Singapore, Singapore. Received November 4, 1966

**Abstract:** Structures 4 and 5, respectively, were assigned to kopsingine and kopsaporine, the two major alkaloids of *Kopsia singapurensis*. The carbon skeleton of kopsingine was confirmed by conversion to 17-methoxy-N-methyl-aspidofractinine, and the assignment of functional groups was based on the mass spectra of kopsingine and numerous derivatives. Kopsaporine was shown to be demethoxykopsingine by a comparison of its mass and nmr spectra with data from kopsingine.

Kopsingine, kopsaporine, and kopsingarine have been reported to occur as the major alkaloidal constituents of *Kopsia singapurensis*.<sup>2</sup> These alkaloids amount to 3% of the dried leaves of this Malayan species, with kopsingine being obtained in 2.2% yield. It will be shown that these compounds are structurally related to several *Kopsia* alkaloids, but their presence

has not been detected in other *Kopsia* species.

Earlier work<sup>3</sup> on the structure of kopsingine established a molecular composition of  $C_{24}H_{28}N_2O_7$ , which has now been confirmed by an accurate mass determination (calcd 456.1896, found 456.1860). The ultraviolet spectrum of kopsingine [ $\lambda_{max}^{MeOH}$  217 m $\mu$  (log  $\epsilon$  4.56), 253 (4.04), 282 (3.38), 288 (3.36)] is similar to reported N-carbomethoxyindoline spectra [pleiocarpine (1)<sup>3,4</sup>  $\lambda_{max}$  207 m $\mu$  (log  $\epsilon$  4.49), 246 (4.20), 283 (3.51), 290

(3.48); kopsine (2)<sup>5</sup>  $\lambda_{\text{max}}$  240 m $\mu$  (log  $\epsilon$  4.08), 278 (3.37), 285–286 (3.35)].

The presence of a hydrogen-bonded urethan group could be deduced from absorption in the infrared at 1670  $\text{cm}^{-1}$ . This is analogous to the kopsine (2) infrared absorption at 1679  $\text{cm}^{-1}$ ,<sup>5</sup> whereas a free urethan [e.g., pleiocarpine (1)] absorbs near 1705  $\text{cm}^{-1}$ .<sup>5</sup> The infrared spectrum of kopsingine shows additional absorption at 1740  $\text{cm}^{-1}$ , which was attributed to an ester function. These two carbomethoxyl groups could be chemically verified by their reduction with lithium aluminum hydride, a reaction which will be discussed in greater detail later.

Conventional analysis had indicated the presence of three methoxyl groups,<sup>3</sup> also apparent in the nmr spectrum of kopsingine at 3.77, 3.79, and 3.82 ppm. Two of these were accounted for by the carbomethoxyl groups. The third had the chemical shift of an aromatic methoxyl, an assignment which is consistent with the observation of only three aromatic hydrogens in the nmr spectrum (6.6–7.2 ppm) and which may explain the small differences between the ultraviolet spectra of kopsingine and the unsubstituted reference compounds cited above.

The nmr spectrum of kopsingine showed absorption of two vinyl protons at 5.62 and 5.95 ppm. These signals were absent in the spectrum of dihydrokopsingine (mol wt, 458), obtained by catalytic hydrogenation of kopsingine. The vinyl protons were coupled to each other ( $J = 10$  cps), and one of these protons (5.95 ppm) was further split by two adjacent non-equivalent protons ( $J = 4$  and 2 cps), the latter appearing as a multiplet at 3.3 ppm. These observations are nearly identical with data on the *Vinca* alkaloid vindoline, to which structure 3 had been assigned.<sup>6</sup>

Kopsingine contained two active hydrogen atoms, as demonstrated by conventional analysis as well as by the incorporation of two deuterium atoms when introduced into the mass spectrometer in the presence of deuterium oxide. The remaining two oxygens of kopsingine, thus far unidentified, may therefore be accounted for as hydroxyl groups. Only one hydroxyl was reactive, since a monoacetate could readily be prepared (mol wt, 498; nmr 1.92 ppm, 3 H). It was also apparent that this hydroxyl was secondary, as the nmr spectrum

of kopsingine acetate showed a one-proton signal at 5.15 ppm (a doublet due to long-range coupling,  $J = 2$  cps) from the proton on the carbon bearing the acetate group. The infrared absorption of the acetate at 1670  $\text{cm}^{-1}$  indicated that the second hydroxyl, probably tertiary, was responsible for the hydrogen bonding of the urethan.

Because of the striking similarity of the data for kopsingine and vindoline (3), structure 4 for kopsingine was proposed as a working hypothesis. Confirmation of this structure, including the exact position of aromatic substitution and the relative stereochemistry, resulted from data discussed in the remainder of this paper.<sup>7</sup> An alternative location of the double bond at C-7–C-8 was not consistent with the nmr spectrum of kopsingine, which indicated that the methylene group (3.3 ppm) next to the double bond was further deshielded by an adjacent nitrogen atom. A double bond at C-6–C-7 has also been found in vindolinine,<sup>8</sup> tabersonine,<sup>9</sup> vindoline,<sup>6</sup> and venalstonine.<sup>10</sup>

Structure 4 is supported by the mass spectra of kopsingine and dihydrokopsingine (7). These spectra however are not very characteristic and involve mainly the losses of elements of the C-3–C-4 bridge.

Conclusive evidence for the proposed structure for kopsingine was obtained by the chemical transformations below.

**The Carbon Skeleton and Its C-3 Substituents.** A crucial piece of evidence is the conversion of kopsingine to a compound representing a known ring system by a sequence of a few uncomplicated reactions outlined in Scheme I.

On treatment with *p*-toluenesulfonyl chloride, dihydrokopsingine (7) formed a monotosylate 9 (nmr 2.45 ppm, 3 H). Reduction of the tosylate with lithium aluminum hydride yielded two major products: (a) a diol 10 (mol wt, 370) formed by displacement of the tosylate ester, and (b) a triol 11 (mol wt, 386) formed by cleavage of the S–O bond. The number of hydroxyl groups in each derivative was verified by exchange with deuterium oxide which resulted in a shift of the molecular ions of these compounds to  $m/e$  372 and 389, respectively.

(7) To simplify discussion of the data and arguments, the substituents are always shown at C-3 and C-4 (see structure 4). It should be kept in mind that most of the arguments would hold equally well if they were on C-21 and C-20. The correctness of the former representation will be proven later in this paper.

Scheme I

The triol 11 was also obtained in the hydride reduction of dihydrokopsingine. Conversion of the urethan to an N-methyl group was apparent from the presence of an appropriate signal at 3.12 ppm in the nmr spectrum, and the incorporation of five deuterium atoms (12, mol wt, 391) with lithium aluminum deuteride confirmed the nature of this reaction. The ultraviolet spectrum of the triol 11 [ $\lambda_{\text{max}}^{\text{MeOH}}$  216 m $\mu$  (log  $\epsilon$  4.40), 260 (3.87), 295 (3.34)], as well as the diol and all other N-methyl derivatives, was similar in both peak positions and shape of curve to spectra of N-methylindolines substituted at the position *ortho* to the nitrogen. A suitable model is 1,2,3,4,10,11-hexahydro-8-methoxy-9,11-dimethylcarbazole (8) which exhibits  $\lambda_{\text{max}}$  253 m $\mu$  (log  $\epsilon$  3.86) and 293 (3.18).<sup>11</sup> This observation established the aromatic methoxyl group of

kopsingine at C-17 (see structure 4 for numbering system).

The above-mentioned diol 10 proved to be a 1,2 diol, as it reacted with sodium periodate to give the ketone 13 (mol wt, 338;  $\gamma_{\text{max}}$  1720  $\text{cm}^{-1}$ ). The latter gave a

(11) M. F. Millson and R. Robinson, *J. Chem. Soc.*, 3362 (1955).

monodeuterated alcohol (15, mol wt, 341) on reduction with lithium aluminum deuteride, and the compound 16 (17-methoxy-N-methylaspidofractinine) on Wolff-Kishner reduction. The evidence on which these assignments are based will be outlined below.

The mass spectrum of the diol 10 (mol wt, 370) was consistent with the structure proposed. In particular, the most intense peak at  $m/e$  110 is characteristic<sup>12,13</sup> of alkaloids of the aspidofractinine skeleton (18) which have a hydrogen-bearing substituent (such as a hydroxyl group) at C-3, but lack functional groups at C-4.

Ketone 13 gave a mass spectrum which was consistent with the proposed structure. The most abundant fragment of this spectrum was at  $m/e$  215, and did not contain C-4 ( $m/e$  215 from 14 rather than  $m/e$  217). It seemed likely that homolytic cleavage at C-3-C-4 and C-10-N<sub>b</sub> of an  $M - \text{C}_2\text{H}_4$  ion could produce an ion of mass 215, which then might cyclize to form the fragment a, as diagrammed below.

The position of the carbonyl group in the ketone 13, and hence of the tertiary hydroxyl and carbo-methoxyl functions of kopsingine, was confirmed by conversion to the deuterated alcohol 15. The mass spectrum of the latter is analogous to that of compound 21<sup>12,13</sup> (except the difference of 14 mass units in some of the peaks) with the most intense peak at  $m/e$  110 (characteristic of a C-3 alcohol) and the second major peak at  $m/e$  125. The occurrence of the latter peak at  $m/e$  125 rather than 124 conclusively proved that deuterium was introduced at C-3, since only the substituent  $R_1$  in 21 was found to be transferred in the formation of this ion.<sup>12,13</sup>

18,  $R_1 = R_2 = R_3 = \text{H}$   
 19,  $R_1 = \text{OCH}_3$ ;  $R_2 = R_3 = \text{H}$   
 20,  $R_1 = \text{OCH}_3$ ;  $R_2 = \text{OH}$ ;  $R_3 = \text{H}$   
 21,  $R_1 = \text{OCH}_3$ ;  $R_2 = \text{OH}$ ;  $R_3 = \text{D}$

Figure 1. Mass spectrum of 17-methoxy-N-methylaspidofractinine (16).

The relative stereochemistry at C-3 of kopsingine follows from the observation that only the epimer indicated by structure 4 brings the C-3 hydroxyl group and the urethan carbonyl function close enough to form a hydrogen bond.

The most conclusive verification of the skeleton of kopsingine was provided by a mass spectrum of the reduction product 16 (Figure 1), which showed all the peaks characteristic of the aspidofractinine skeleton. This spectrum is very similar to the published spectra of aspidofractinine itself (18) and 17-methoxyaspidofractinine (19),<sup>18</sup> except for the shifts of all ions containing aromatic substituents, occurring at  $m/e$  324 (M), 296, and 202, and the minor differences in relative peak intensities which are to be expected.

**Location of the C-4 Hydroxyl Function.** Another part of structure 4 which required confirmation was the location of the secondary hydroxyl, suggested to be at C-4, and this was achieved through the reactions of the triol 11 (Scheme II).

Scheme II

Treatment of triol 11 with sodium periodate gave a mixture of products, the formation of which is unusual in many respects. It was immediately apparent that cleavage at C-3-C-4 had not occurred, probably be-

cause the intermediate five-membered periodate ring might interfere with either the 20-21 or the 10-11 bridge. However, the primary alcohol function in 11 was readily lost, resulting in an  $\alpha$ -diketone 27, an  $\alpha$ -ketol 24, and a comparatively small quantity of an unstable compound thought to be the enediol 23. The properties of these products thus require the presence of a secondary hydroxyl group at a carbon atom next to that bearing the tertiary hydroxyl of kopsingine.

The diketone 27 (mol wt, 352;  $\gamma_{\text{max}}$  1720, 1755  $\text{cm}^{-1}$ ) was isolated as orange needles, mp 184-187°. It resulted either from air oxidation of the ketol 24 or, more likely, from the enediol 23, since the latter was observed to give nearly equal amounts of 24 and 27 on standing.

The ketol (mol wt, 354;  $\gamma_{\text{max}}$  1715  $\text{cm}^{-1}$ ) was originally thought to have structure 22, with a ketone function at C-3. However, its mass spectrum had a major peak at  $m/e$  124, a result which was shown earlier to require a hydrogen atom at C-3.<sup>12,13</sup> Furthermore, the monodeuterated derivative 25, obtained by base-catalyzed exchange with deuterium oxide, produced a shift of the major part of this peak to  $m/e$  125. In addition, a significant ion of  $m/e$  203 from the ketol was shifted to  $m/e$  204 in the spectrum of 25 and to  $m/e$  205 when deuterium was also incorporated in the hydroxyl group (26). The fragment at  $m/e$  203 must have structure b, containing C-3 as well as the oxygen function at that carbon. The two deuterium atoms can only be incorporated in this fragment if the C-3 function is a secondary alcohol, and the ketol therefore is best represented by structure 24. Isolation of the ketol in this form suggests that the isomerization of 22 to 24 takes place readily *via* the enediol intermediate, which relieves the steric crowding of a tetrahedral carbon at C-4. The preference for a trigonal carbon at C-4 is also indicated from an examination of Dreiding models.

The diketone and the ketol were directly correlated by hydride reduction of each to the same diol 29. Use of deuteride gave two labeled diols, 30 and 31. The mass spectra of these gave additional confirmation of the structure 24 for the ketol. In particular, the peaks at  $m/e$  124 and 204 (c) in the spectrum of 29 were shifted to  $m/e$  125 and 205 only in the spectrum of the diol-*d*-31 derived from the diketone, which implied that the deuterium atom in 30, obtained from the ketol, was located at C-4.

The diketone 27 was originally considered a suitable starting material for the preparation of compound 16 by Wolff-Kishner reduction; however, the single product obtained proved instead to be the alcohol 28. Further investigation of this reaction showed that only a monohydrazone had formed, and the remaining

ketone function at C-4 subsequently became reduced (presumably from the less hindered side) by the alkoxide during pyrolysis. These results again point to an unusual environment of C-4, also noticed in the isomerization of the  $\alpha$ -ketols, which could perhaps also be related to the failure of the C-3-C-4 periodate cleavage of the triol 11.

The reluctance of the C-4 ketone function to form a hydrazone may also account for the formation of alcohol 32 by Wolff-Kishner reduction of 24. The mass spectrum of 32 was distinctly different from that of the isomeric alcohol 15 (hydrogen instead of deuterium at C-3), the expected reduction product. In fact, the spectra of 28 and 32 were strikingly similar (peaks at  $m/e$  188, 125, and 124) with only small differences in relative peak intensities, reflecting the epimerization at C-4. If a C-4 carbonyl function is unreactive toward hydrazine, the ketol 24 could have been isomerized to form the hydrazone of 22. The product could then undergo normal Wolff-Kishner reduction to the less hindered C-4 epimer 32.

A second major product of the Wolff-Kishner reduction of the ketol 24 arose by an abnormal reaction, which is also occasionally observed with  $\alpha$ -substituted hydrazones,<sup>14</sup> in which the  $\alpha$  substituent (a hydroxyl group in this case) is lost to give an olefin 33. The mass spectrum of this compound shows a very pronounced loss of ethylene, facilitated by the extended conjugation of the resulting ion d ( $m/e$  294). The nmr spectrum of 33 exhibited two doublets for the resonance of two olefinic protons (6.08 and 6.45 ppm,  $J = 9$  cps), which confirmed the assignment of an isolated double bond on one of the ethylene bridges.

Catalytic reduction of the olefin 33 completed an independent route to the previously derived 17-methoxy-N-methylaspidofractinine (16), thereby verifying all features of the structure of kopsingine, with the exception of the still uncertain relative stereochemistry at C-4.

**Substituents at C-3-C-4 vs. C-21-C-20.** The remaining possibility that the substituents are located at C-21-C-20 is eliminated by the following observations.

It had been noticed in substituted derivatives of aspidofractinine that the unsubstituted bridge (that which is *trans* to the tryptophan bridge) was always lost in the formation of the  $M - 28$  ion.<sup>12,13</sup> This feature, which is also evident in the mass spectra of many kopsingine derivatives, was tentatively taken as an indication that here also the substituents are at the same (*cis*) bridge. The preparation of the deuterated derivative 17 strengthened this hypothesis. Base-catalyzed exchange of ketone 13 with deuterium oxide gave the labeled derivative 14, which was reduced by a Wolff-Kishner reaction in methanol-*d*. The mass spectrum of the product 17 had peaks at  $m/e$  328 ( $M$ ), 300, 204, 190, 125, and 111, indicating the exclusive

(14) N. J. Leonard and R. C. Sentz, *J. Am. Chem. Soc.*, **74**, 1704 (1952), and references therein.

loss of a completely unlabeled bridge. It will be shown by comparison with compounds known to be oxygenated at C-20 that in kopsingine the substituents are at C-3 and C-4, *i.e.*, at the *cis* bridge. As a corollary, the spectrum of 17 implies that the preferred loss of one of the two bridges is controlled by its stereochemistry and not by the presence or absence of substituents.<sup>15</sup>

A comparison of the mass spectra of alcohols 28 and 32 [ $m/e$  340 ( $M$ ), 312 ( $M - 28$ ), 188, 125, 124] with that of compound 34 [ $m/e$  296 ( $M$ ), 252 ( $M - 44$ ), 140, 109<sup>16</sup>] provided additional evidence for the presence of the functional groups of kopsingine at the C-3-C-4 bridge. In each case, only the bridge *trans* to the tryptophan bridge was lost, even though this was the substituted bridge in 34 ( $M - 44$ ) and the unsubstituted bridge in 28 and 32 ( $M - 28$ ). Because of the significant implications of this result, it was necessary to make very certain that the pair 28 and 32 have the substituents indeed on the other bridge in comparison with 34. Three of the four possible alcohols with the hydroxyl groups on the same bridge (15, 28, and 32) have been obtained from kopsingine. The possibility that 23 could be the fourth, and that 28 and 32 could be C-21

alcohols and 15 could be the C-20 epimer of 34, would require the ketones 13 and 35 to be nearly identical.

(15) The exclusiveness of the loss of one bridge eliminates a stepwise process initiated by cleavage of the C-12-C-19 bond (which is both benzylic and  $\alpha$  to nitrogen) because both bridges become equivalent if the resulting radical ion has sufficient lifetime for C-12 and C-19 to become planar. On the other hand, a stepwise mechanism involving initial cleavage at C-2-C-21 is not only consistent with all data but also accounts for the stereospecificity of the elimination of ethylene. This cleavage and the subsequent planar configuration of the bonds at C-2 release the considerable strain of the bridged ring system, whereas the alternative cleavage at C-2-C-3 not only leads to increased ring strain, but also greater steric crowding between C-4 and C-10.

(16) H. K. Schnoes and K. Biemann, *J. Am. Chem. Soc.*, **86**, 5693 (1964).

This was ruled out by a comparison of their mass spectra which were dissimilar far beyond the degree attributable to their difference in aromatic substitution [13:  $m/e$  338 (M), 215 (a), 187, 169, 155, 124; 35:  $m/e$  294 (M), 266 (M - CO and M - C<sub>2</sub>H<sub>4</sub>), 252 (M - C<sub>2</sub>H<sub>5</sub>O), 138, 109<sup>16</sup>]. It follows that the ketone functions of 13 and 35 must be on different bridges, and the kosingine derivatives are therefore substituted at C-3 and/or C-4.

**Kopsaporine and Kopsingarine.** Kopsaporine, a second major alkaloid of *Kopsia singapurensis*, has a composition of C<sub>23</sub>H<sub>28</sub>N<sub>2</sub>O<sub>6</sub>, based on conventional analysis and mass spectrometric molecular weight. The mass spectrum suggested it to be demethoxykopsingine (5) because it was analogous to the spectrum of kopsingine except that all peaks above  $m/e$  200 appeared 30 mass units lower. All other evidence agreed with this assignment. Analysis had indicated the presence of two methoxyl groups which, by analogy with kopsingine, could be attributed to a hydrogen-bonded urethan and an ester ( $\nu_{\max}$  1675 and 1740 cm<sup>-1</sup>; nmr 3.80 and 3.90 ppm). The nmr spectrum of kopsaporine showed the same olefinic absorption pattern [5.83 ( $J$  = 10 cps) and 6.02 ppm ( $J$  = 10, 4, and 2 cps)] as had been observed for kopsingine, and the ultraviolet spectrum [ $\lambda_{\max}^{\text{MeOH}}$  207 m $\mu$  (log  $\epsilon$  4.53), 246 (4.15), 279 (3.43), 287 (3.39)] was similar to the spectra of pleiocarpine (1)<sup>4</sup> and kopsine (2).<sup>5</sup> Three active hydrogens had been indicated by conventional analysis; however, only two deuterium atoms were incorporated by exchange with deuterium oxide in the mass spectrometer.

Further proof is the appearance of a fourth aromatic hydrogen in the nmr spectrum of kopsaporine, which was distinctive in its absorption as a broad doublet (7.53 ppm,  $J$  = 8 cps) slightly downfield from the remaining aromatic signals. This behavior is characteristic of the C-17 hydrogen atom of other N-carbomethoxyindoline alkaloids (cf. pleiocarpine<sup>4</sup>). Lack of this signal in the spectrum of kopsingine provides, in retrospect, complementary evidence for the assignment of a methoxyl group at C-17 in this alkaloid.

It is suggested that kopsingarine, also isolated from *K. singapurensis*, is 17-hydroxykopsaporine (6). This follows from a comparison of ultraviolet and infrared spectra of kopsingarine with data from kopsingine and kopsaporine.<sup>2</sup> Structure 6 is also in agreement with the elemental analysis of C<sub>23</sub>H<sub>28-30</sub>N<sub>2</sub>O<sub>7</sub>, including the presence of only two O-methyl groups. However, neither chemical nor mass spectral data have yet been obtained.

## Experimental Section

Reaction products were usually purified by preparative thin layer chromatography (tlc) on silica gel H (Brinkmann), prewashed with methanol, using chloroform-methanol (9:1) as the solvent system. Compounds were detected with iodine vapor. The small scale on which reactions were frequently performed often precluded crystallization, and thus many compounds were characterized primarily by infrared, ultraviolet, and mass spectra.

Melting points were taken on a Kofler micro hot stage, and are uncorrected. Quantitative ultraviolet spectra were determined with a Cary Model 14 recording spectrophotometer, and those reported without extinction values were determined with a Cary Model 11 spectrophotometer. Infrared spectra were obtained using either a Perkin-Elmer Model 237B or Model 337 spectrophotometer. Nmr spectra were obtained in deuteriochloroform with a Varian A-60 spectrometer, and data are expressed in parts per million downfield from an internal tetramethylsilane standard.

Conventional mass spectra were determined with a CEC 21-103C mass spectrometer, equipped with a vacuum lock for the introduction of compounds of low volatility or thermal instability directly into the ion source. All spectra were recorded at 70 ev ionizing potential. High-resolution data were obtained with a CEC 21-110 double-focusing mass spectrometer, using a photographic plate for recording.

The spectral data reported here for kopsingine and kopsaporine were determined recently and some of them differ slightly from those previously reported,<sup>2</sup> which is due to the use of different instruments.

**Isolation of Alkaloids.** The isolation, reported in detail elsewhere,<sup>2</sup> involved alumina chromatography of the bases, obtained from a methanol extract of the leaves of *Kopsia singapurensis*. After separation of crystalline kopsingine from the early fractions, the remaining residue was subjected to countercurrent distribution giving kopsaporine, kopsingarine, and additional kopsingine.

**Kopsingine (4).** Recrystallization from chloroform-ethanol gave colorless prisms: mp 270-274° dec;  $pK_a$  = 5.27;  $[\alpha]_D^{25} +75^\circ$ ;  $\lambda_{\max}^{\text{MeOH}}$  217 m $\mu$  (log  $\epsilon$  4.56), 253 (4.04), 282 (3.38), 288 (3.36);  $\nu_{\max}^{\text{CHCl}_3}$  1670, 1740, 3370 cm<sup>-1</sup>; nmr 3.3 [multiplet, (C-8) H], 3.77 (singlet, OCH<sub>3</sub>), 3.79 (singlet, OCH<sub>3</sub>), 3.82 (singlet, OCH<sub>3</sub>), 5.62 [doublet,  $J$  = 10 cps, (C-6) H], 5.73 [singlet, (C-3) OH], 5.95 [octet,  $J$  = 10, 4, and 2 cps, (C-7) H], 6.6-7.2 (multiplet, 3 H), 7.98 ppm [broad doublet,  $J$  = 4 cps, (C-4) OH]; mass spectrum,  $m/e$  456 (M), 428, 427, 405, 397, 395, 379, 368, 339, 337, 283, 246.

**Kopsaporine (5).** Recrystallization from ethanol gave colorless needles: mp 234° dec;  $pK_a$  = 5.63;  $[\alpha]_D^{25} +48^\circ$ ;  $\lambda_{\max}^{\text{MeOH}}$  207 m $\mu$  (log  $\epsilon$  4.53), 246 (4.15), 279 (3.43), 287 (3.39);  $\nu_{\max}^{\text{CHCl}_3}$  1675, 1740, 3350 cm<sup>-1</sup>; nmr 3.4 [multiplet, (C-8) H], 3.80 (singlet, OCH<sub>3</sub>), 3.90 (singlet, OCH<sub>3</sub>), 5.83 [doublet,  $J$  = 10 cps, (C-6) H], 6.02 [octet,  $J$  = 10, 4, and 2 cps, (C-7) H], 6.32 [singlet, (C-3) OH], 7.0-7.4 (multiplet, 3 H), 7.53 [complex doublet,  $J$  = 8 cps, (C-17) H], 8.15 ppm [broad doublet,  $J$  = 5 cps, (C-4) OH]; mass spectrum,  $m/e$  426 (M), 398, 397, 375, 367, 365, 349, 338, 309, 307, 253, 216, 156, 143, 130, 115, 108.

**Kopsingine Acetate.** Kopsingine (50 mg) and 50  $\mu$ l of acetic anhydride were refluxed for 24 hr in 2 ml of pyridine. The product was evaporated to dryness under vacuum and the residue purified by tlc to give amorphous kopsingine acetate;  $\nu_{\max}^{\text{CHCl}_3}$  1665, 1740, 3320 cm<sup>-1</sup>; nmr 1.92 (singlet, CH<sub>3</sub>CO), 3.67 (singlet, OCH<sub>3</sub>), 3.77 (singlet, OCH<sub>3</sub>), 3.80 (singlet, OCH<sub>3</sub>), 5.15 [doublet,  $J$  = 2 cps, (C-4) H], 5.63 [(C-6) H], 5.78 [(C-7) H], 6.27 [singlet, (C-3) OH], 6.6-7.2 ppm (3 H); mass spectrum,  $m/e$  498 (M), 479, 455, 439, 421, 379, 337, 283, 123, 120, 107.

**Dihydrokopsingine (7).** Kopsingine (1.00 g), with 200 mg of platinum oxide in 50 ml of acetic acid-methanol (4:1), was reduced with hydrogen gas for 3 hr at room temperature and atmospheric pressure. After removal of platinum by filtration, the methanol was evaporated and 20 ml of water was added. The solution was made basic with sodium carbonate and then extracted with three 20-ml portions of chloroform. The extracts were combined, evaporated, and crystallized from chloroform-methanol to give 884 mg of dihydrokopsingine (7) as colorless prisms: mp 268-270° dec;  $\lambda_{\max}^{\text{MeOH}}$  216 m $\mu$  (log  $\epsilon$  4.58), 253 (4.06), 281 (3.38), 288 (3.36);  $\nu_{\max}^{\text{CHCl}_3}$  1670, 1740, 3400 cm<sup>-1</sup>; nmr 3.80 (singlet, 6 H, OCH<sub>3</sub>), 3.82 (singlet, OCH<sub>3</sub>), 5.62 [singlet, (C-3) OH], 6.6-7.2 (3 H), 8.44 ppm [doublet,  $J$  = 7 cps, (C-4) OH]; mass spectrum,  $m/e$  458 (M), 443, 430, 429, 399, 370, 355, 341, 399, 315, 301, 278, 124, 122, 109.

**Dihydrokopsingine Tosylate (9).** Dihydrokopsingine (7, 50 mg) and 25 mg of *p*-toluenesulfonyl chloride were dissolved in 0.5 ml of pyridine and allowed to stand at room temperature for 24 hr. The solvent was removed under vacuum and the residue taken up in 5 ml of chloroform. This solution was rinsed successively with two 5-ml portions each of water, 0.5 N HCl, and saturated aqueous sodium carbonate, then dried over sodium sulfate and evaporated. The amorphous residue was not further purified and was identified as dihydrokopsingine tosylate on the basis of its nmr spectrum: 2.45 (tosylate CH<sub>3</sub>), 3.45 (OCH<sub>3</sub>), 3.74 (OCH<sub>3</sub>), 3.80 (OCH<sub>3</sub>), 4.90 [singlet, (C-4) H], 5.90 [singlet, (C-3) OH], 6.6-7.2 (3 H), 7.1-7.9 ppm (quartet, 4 H).

**Hydride Reduction of Dihydrokopsingine to Triol 11.** Dihydrokopsingine (7, 650 mg) and 350 mg of lithium aluminum hydride were refluxed for 4 hr in 50 ml of tetrahydrofuran. Excess hydride was decomposed with THF containing water, then solvents were removed by evaporation. Saturated sodium potassium tartrate solution (100 ml) was added, and the product was then extracted with three 50-ml portions of chloroform. After evaporation of the combined extracts, crystallization from ether yielded 375 mg of triol 11 as colorless needles. Recrystallization from ether gave:

$-71^\circ$ ;  $\lambda_{\text{max}}^{\text{MeOH}}$  216  $\mu\text{m}$  ( $\log \epsilon$  4.40), 260 (3.87), 295 (3.34);  $\nu_{\text{max}}^{\text{CHCl}_3}$  540  $\text{cm}^{-1}$ ; nmr 3.12 (singlet,  $\text{NCH}_3$ ), 3.75 (singlet,  $\text{OCH}_3$ ), doublet,  $J = 12$  cps, one of the two hydroxymethylene hydrogens C-3 with geminal coupling, 6.70 ppm (singlet, 3 H); spectrum,  $m/e$  386 (M), 355, 327, 297, 271, 230, 216, 202, 188, 14, 126, 125, 124, 112, 96.

**Triol- $d_3$ .** When triol 11 was introduced into the mass spectrometer in the presence of deuterium oxide, the mass spectrum at of triol-(O- $d_3$ ) with peaks at  $m/e$  389 (M), 357, 329, 298, 11, 217, 203, 189, 174, 156, 128, 126, 124, 114, 97.

**Diol- $d_6$  (12).** Use of lithium aluminum deuteride in the reduction of dihydrokopsingine gave triol- $d_3$  (12): mass spectrum, 1 (M), 358, 330, 300, 274, 235, 221, 205, 191, 177, 154, 126, 2, 96.

**Reduction of Dihydrokopsingine Tosylate to Diol 10.** Dihydrokopsingine tosylate (approximate 50 mg) in 5 ml of tetrahydrofuran was refluxed for 2 hr with excess lithium aluminum hydride. The solvent was then evaporated and 50 ml of saturated potassium tartrate solution was added. Two 10-ml portions with chloroform, followed by tlc purification, gave 10 mg of diol 10 as the major product, with a smaller amount of triol 11. The amorphous diol had  $\nu_{\text{max}}^{\text{CHCl}_3}$  3380  $\text{cm}^{-1}$ ; mass spectrum, 0 (M), 355, 339, 311, 124, 122, 110, 96.

**Periodate Cleavage of Diol 10 to Ketone 13.** Diol 10 (9 mg) in 10 ml of methanol was added to 2 ml of 0.01% sulfuric acid solution which contained 40 mg of sodium periodate and 0.4 ml of water. The mixture was stirred at room temperature for 15 min and then poured into 10 ml of saturated sodium carbonate solution. Extractions of 5 ml of chloroform each, followed by tlc purification, gave 2 mg of ketone 13:  $\nu_{\text{max}}^{\text{CHCl}_3}$  1720  $\text{cm}^{-1}$ ; mass spectrum,  $m/e$  338 (M), 215 (a), 187, 155, 124.

**Ketone 13 to Ketone 14.** Ketone 13 (2 mg) was dissolved in 1 ml of tetrahydrofuran. Deuterium oxide (0.1 ml) and a small piece of sodium metal were added, and the solution was stirred at room temperature for 1 hr. The sodium hydroxide layer was removed and 200  $\mu\text{l}$  of deuterium oxide and additional sodium were added. After a further 18 hr with stirring, the tetrahydrofuran was evaporated. Deuterium oxide (5 ml) was added and the product extracted with 5-ml portions of chloroform to give ketone- $d_3$  14: mass spectrum,  $m/e$  340 (M), 215, 187, 156, 126.

**Reduction of Ketone 13 to Alcohol 15.** Ketone 13 was dissolved in 0.5 ml of tetrahydrofuran and excess lithium aluminum deuteride was added. After 3 hr at room temperature, the solvent was evaporated and 5 ml of saturated sodium potassium tartrate solution was added. Extraction with 5 ml of chloroform gave the pure deuterated alcohol 15: mass spectrum,  $m/e$  341 (M), 215, 187, 156, 126.

**Wolff-Kishner Reduction of Ketone 13 to 17-Methoxy-N-methylfractinine (16).** Ketone 13 (2 mg) was dissolved in 200  $\mu\text{l}$  of methanol. Hydrazine hydrate (20  $\mu\text{l}$ ) was added, and the solution was heated in a sealed tube for 5 hr at  $100^\circ$ . The ethanol was removed and 100  $\mu\text{l}$  of 10% sodium hydroxide in ethanol was added. This mixture, sealed, was kept at  $190^\circ$  for 5.5 hr. Water was added, and the product was extracted with two 5-ml portions of chloroform to give pure 17-methoxy-N-methylaspidospermatine (16):  $\lambda_{\text{max}}^{\text{MeOH}}$  218, 258, 293  $\mu\text{m}$ ; mass spectrum, Figure 1.

**Wolff-Kishner Reduction of Ketone 14 to 17-Methoxy-N-methylfractinine- $d_3$  (17).** Ketone 14 (2 mg) was dissolved in 100  $\mu\text{l}$  of methanol- $d_4$  and added to 100  $\mu\text{l}$  of methanol- $d_4$  containing 10% sodium hydroxide. The solution was heated at  $100^\circ$  for 2 hr and then the solvent was evaporated. A saturated solution (300  $\mu\text{l}$ ) of sodium methoxide in methanol- $d_4$  was added, then sealed and heated at  $200^\circ$  for 4 hr. Water (5 ml) was added, and the product was extracted with two portions of 5-ml chloroform. A mass spectrum indicated a small amount of diol 11 in addition to that at C-3 and C-4, so the product was extracted at  $200^\circ$  for 16 hr in 0.5 ml of sodium ethoxide-ethanol. The product was worked up as above. After purification by tlc, the product gave mass spectral peaks at  $m/e$  328 (M), 300, 204, 190, 125, 111.

**Periodate Cleavage of Triol 11.** Triol 11 (300 mg) in 1 ml of methanol was added to 1.2 g of sodium periodate and 12 ml of water in 60 ml of 0.01% sulfuric acid-methanol. The mixture was stirred at room temperature for 15 min, then poured into 150 ml of saturated sodium carbonate solution. Four chloroform extractions of 25 ml each were combined and evaporated, giving 30 mg of amorphous residue. From 300 mg of this residue, after purification by tlc, three fractions were obtained containing diketone 27, enediol 23, and ketone 24, each described below.

**Ketone 27.** Crystallization from methanol of the least polar fraction from the periodate cleavage of triol 11 gave 45 mg of diketone 27 as orange needles: mp  $184-187^\circ$ ;  $\lambda_{\text{max}}^{\text{MeOH}}$  216  $\mu\text{m}$  ( $\log \epsilon$  4.48), 256 (3.92), 295 (3.45);  $\nu_{\text{max}}^{\text{CHCl}_3}$  1720, 1755  $\text{cm}^{-1}$ ; mass spectrum,  $m/e$  352 (M), 296, 229, 226, 202, 109.

**Ketone 24.** The most polar of the three periodate cleavage fractions crystallized with difficulty from acetone to give 41 mg of ketone 24 as colorless prisms: mp  $190-193^\circ$ ;  $\lambda_{\text{max}}^{\text{MeOH}}$  217  $\mu\text{m}$  ( $\log \epsilon$  4.46), 257 (3.94), 296 (3.41);  $\nu_{\text{max}}^{\text{CHCl}_3}$  1715, 3350  $\text{cm}^{-1}$ ; nmr 3.02 (singlet,  $\text{NCH}_3$ ), 3.42 [singlet, (C-19) H], 3.47 [(C-3) OH], 3.75 (singlet,  $\text{OCH}_3$ ), 4.22 [singlet, (C-3) H], 6.6-7.1 ppm (3 H); mass spectrum,  $m/e$  354 (M), 337, 326, 297, 203 (b), 124, 110, 96.

**Ketone- $d_3$  25.** Ketone 24 was dissolved in 1 ml of tetrahydrofuran with 100  $\mu\text{l}$  of deuterium oxide. A small piece of sodium metal was added and the solution was allowed to stand at room temperature for 13 hr. The solvent was evaporated, 1 ml of deuterium oxide was added, and the product was extracted with 5 ml of chloroform. After purification by tlc, ketone- $d_3$  25 was obtained: mass spectrum,  $m/e$  355 (M), 338, 327, 297, 204 (b'), 125, 110, 96.

**Ketone- $d_3$  26.** When ketone- $d_3$  25 was introduced into the mass spectrometer in the presence of deuterium oxide, the following mass spectrum was obtained:  $m/e$  356 (M), 338, 328, 298, 205 (b'), 125, 111, 97.

**Enediol 23.** The third fraction from the periodate cleavage of triol 11 could not be isolated or characterized in pure form. Even though chromatographic resolution was good, on repeated chromatography this fraction always contained large amounts of diketone 27 and ketone 24, which must have formed by decomposition of the compound in question. The structure of an enediol 23 is postulated for this compound. An alternative ketone structure 22 cannot be ruled out, but it seems that the enediol would be more stable because of the trigonal carbon at C-4, and a stable 3,4 double bond has also been observed in the olefin 33.

**Diol 29. a.** Diketone 27 (5 mg) with excess lithium aluminum hydride was allowed to stand at room temperature in 1 ml of tetrahydrofuran for 3 hr. The solvent was then evaporated and 5 ml of saturated sodium potassium tartrate was added. The product was extracted with two 5-ml portions of chloroform and crystallized from methanol to give colorless needles: mp  $169-171^\circ$ ;  $\nu_{\text{max}}^{\text{CHCl}_3}$  3400  $\text{cm}^{-1}$ ; mass spectrum,  $m/e$  356 (M), 297, 204 (c), 154, 126, 124, 112.

**b.** Ketone 24 (5 mg) was reduced with hydride in the same manner, giving a product identical with the diol 29 from the diketone (mp  $169-171^\circ$ , identical infrared and mass spectra).

**Diol- $d_3$  30.** Ketone 24 was reduced as above, using lithium aluminum deuteride, giving diol- $d_3$  30: mass spectrum,  $m/e$  357 (M), 297, 204 (c), 155, 127, 124, 113.

**Diol- $d_3$  31.** Diketone 27 was reduced as above, using lithium aluminum deuteride, giving diol- $d_3$  31: mass spectrum,  $m/e$  358 (M), 297, 205 (c), 155, 127, 125, 113.

**Wolff-Kishner Reduction of Diketone 27 to Alcohol 28.** Diketone 27 (5 mg) and 5  $\mu\text{l}$  of anhydrous hydrazine in 100  $\mu\text{l}$  of ethanol was heated in a sealed tube at  $100^\circ$  for 3 hr. Evaporation under vacuum gave the monohydrazone: mol wt, 366;  $\nu_{\text{max}}^{\text{CHCl}_3}$  1665  $\text{cm}^{-1}$  (chelated carbonyl). The hydrazone was dissolved in 100  $\mu\text{l}$  of ethanol and 100  $\mu\text{l}$  of a saturated solution of sodium ethoxide in ethanol was added. The reaction mixture was heated in a sealed tube at  $200^\circ$  for 4 hr. Water (5 ml) was then added, and the major product, alcohol 28, was extracted with two 5-ml portions of chloroform, purified by tlc, and crystallized from methanol as colorless needles: mp  $204-205^\circ$ ; mass spectrum,  $m/e$  340 (M), 312, 188, 125, 124.

**Wolff-Kishner Reduction of Ketone 24 to Alcohol 32 and Olefin 33.** Ketone 24 (60 mg) in 0.5 ml of ethanol was heated at  $100^\circ$  in a sealed tube for 3 hr with 50  $\mu\text{l}$  of anhydrous hydrazine. A saturated solution of sodium ethoxide in ethanol (0.5 ml) was added, and the mixture was then heated for 4 hr in a sealed tube at  $200^\circ$ . Water (25 ml) was added and the product was extracted with two 25-ml portions of chloroform. Separation by tlc provided two major products, alcohol 32 and olefin 33.

**a.** Alcohol 32 (9 mg) was crystallized from methanol to give 5 mg of colorless prisms: mp  $172-174^\circ$ ;  $\lambda_{\text{max}}^{\text{MeOH}}$  217  $\mu\text{m}$  ( $\log \epsilon$  4.41), 259 (3.85), 294 (3.37); mass spectrum,  $m/e$  340 (M), 312, 188, 125, 124.

**b.** Olefin 33 (8 mg) was obtained in colorless amorphous form:  $\lambda_{\text{max}}^{\text{MeOH}}$  257, 293  $\mu\text{m}$ ; nmr 3.02 (singlet,  $\text{NCH}_3$ ), 3.77 (singlet,  $\text{OCH}_3$ ), 6.08 (doublet  $J = 9$  cps), 6.45 (doublet,  $J = 9$  cps), 6.6-7.1 ppm; mass spectrum,  $m/e$  322 (M), 294 (d), 279, 266, 250, 238, 224, 161.

**Reduction of Olefin 33 to 17-Methoxy-N-methylaspidospermatine (16).** Olefin 33 (5 mg) in 1 ml of methanol was reduced with hydrogen over platinum at room temperature and pressure for 1 hr. Filtration and evaporation, followed by purification by tlc, yielded

a single amorphous compound which gave a mass spectrum identical with that of 17-methoxy-N-methylaspidofractinine (16), previously obtained from the ketone 13.

**Acknowledgment.** This investigation was supported by a Public Health Service Fellowship (5-FI-GM-21,624-

03) from the National Institute of General Medical Sciences (to D. W. T.) and a research grant of the National Science Foundation (GP 3734). The authors wish to thank Drs. B. Webster and C. Falshaw who performed some of the preliminary experiments.

## Acceleration of Phenyl Ester Cleavage by Cycloamyloses. A Model for Enzymatic Specificity<sup>1,2</sup>

Robert L. VanEtten,<sup>3</sup> John F. Sebastian,<sup>3</sup> George A. Clowes, and Myron L. Bender

*Contribution from the Department of Chemistry, Northwestern University, Evanston, Illinois 60201. Received January 6, 1967*

**Abstract:** The cycloamyloses cause a markedly stereoselective acceleration of phenol release from a variety of substituted phenyl acetates in alkaline solution. Unlike methyl glucoside or glucose which produces small uniform rate effects, both cyclohexaamylose and cycloheptaamylose cause large, nonuniform increases in the rate of phenol release from *meta*-substituted phenyl acetates; phenol release from *para*-substituted phenyl acetates is only slightly enhanced. Rate effects due to cyclooctaamylose are smaller and much less stereoselective. The rate accelerations are independent of the electronic nature of the substituents. The cycloamylose system exhibits many characteristics of enzyme-catalyzed reactions, including saturation, competitive inhibition, and nonproductive binding. Dissociation constants of cycloamylose complexes with a variety of guest molecules were obtained using kinetic, spectroscopic, and competitive inhibition methods and are in experimental agreement. The maximal rate effects are independent of the stabilities of the cycloamylose-substrate complexes, as in enzymatic catalysis. The rate accelerations are entirely explained by considering the region of the cycloamylose torus and the secondary hydroxyl groups to be the active site of the cycloamylose. In the complex the *meta* substituents on the phenyl ring fix the carbonyl carbon atom of the ester in close proximity to the secondary hydroxyl groups of the cycloamylose whereas *para* substituents prevent this approximation. The reaction system constitutes a striking model for the lock and key theory of enzymatic specificity proposed by Emil Fischer.

As an aid to the understanding of the mechanism of enzyme action it would be useful to have a relatively simple model system which exhibits some of the important characteristics of enzyme-catalyzed reactions. Such a model system should exhibit substantial catalytic effects which vary in a predictable manner depending upon the substrate. The catalysis should be ascribable to a known reactive group or groups and the structure and geometry of the catalyst should be known. The catalytic effects should be the result of prior complexation of the catalyst and substrate. It must be possible to accurately determine both the stability of the catalyst-substrate complex and its inherent reactivity since there is no necessary relationship between these two factors (for example, although chymotrypsin binds N-acetyl-D-tryptophanamide somewhat better than it binds the L isomer,<sup>4</sup> the deacylation rates of N-acetyl-D- and -L-tryptophanyl chymotrypsins differ by a factor of  $1.6 \times 10^4$  in favor of the L isomer<sup>5</sup>).

Stereochemical aspects of both the binding and the subsequent catalysis should be readily explainable on the basis of the geometry of the catalyst and substrate. Other features of enzymic catalysis which should be sought for in a model system include competitive inhibition and nonproductive binding. In addition, it would be preferable if the catalysis proceeded by a mechanism similar to those so far known for enzyme-catalyzed reactions.

It appeared possible that a system incorporating the cycloamyloses<sup>6-9</sup> might permit the development of such a model. As the name implies,<sup>10</sup> the cycloamyloses are cyclic  $\alpha$ -1,4-linked D-glucose polymers and have 6, 7, or 8 glucose residues per molecule.<sup>11</sup> X-Ray crystallographic studies have firmly established the structure<sup>7</sup>

chymotrypsin-catalyzed hydrolyses. Conversely, the  $k_2$  step for chymotrypsin-catalyzed hydrolyses of esters related to specific substrates is too fast to permit a similar measurement.

(10) The names  $\alpha$ -,  $\beta$ -, and  $\gamma$ -Schardinger dextrans and cyclodextrins became established early in the literature, the prefixes referring to cyclohexa-, -hepta-, and -octaamylose, respectively. Now that the structures of these molecules have been unequivocally established it seems appropriate to use the more descriptive amylose names.

(11) The structure of the homologous cyclononaamylose also appears to have been established: D. French, A. O. Pulley, J. A. Effenberger, M. A. Rougiev, and M. Abdullah, *Arch. Biochem., Biophys.*, **111**, 153 (1965).

(4) The  $K_s$  for acetyl-L-tryptophanamide is  $5.0 \times 10^{-3}$  M [R. J. Foster and C. Niemann, *J. Am. Chem. Soc.*, **77**, 1886 (1955)] while the  $K_1$  for acetyl-D-tryptophanamide is  $2.3 \times 10^{-3}$  M [R. J. Foster, H. J. Shine, and C. Niemann, *ibid.*, **77**, 2378 (1955)].

(5) D. W. Ingles, J. R. Knowles, and J. A. Tomlinson, *Biochem. Biophys. Res. Commun.*, **23**, 619 (1966). Qualitatively similar observations may be made for  $K_s$ ,  $K_1$ , and  $k_2$  values of amide substrates but because reactions of the D isomers are so slow it is not possible to obtain an accurate ratio which describes the kinetic specificity of the  $k_2$  step for

and stereochemistry<sup>12</sup> of the cycloamyloses. They are doughnut-shaped molecules with the glucose units in the C-1 conformation. The primary hydroxyl groups (carbon 6 of the glucose unit) are located on one side of the torus while the secondary hydroxyls (carbons 2 and 3 of the glucose units) are located on the other side of the torus. The interior of the cavity contains a ring of C-H groups, a ring of glycosidic oxygens, and another ring of C-H groups. As a consequence the interior of the cycloamylose torus is relatively hydrophobic<sup>13</sup> when compared to water.

The cycloamyloses form solid inclusion complexes and complexes in solution with a variety of molecules and ions.<sup>6-9</sup> This characteristic has led to their utilization as enzyme models. For example, the cycloamyloses have been shown to act as asymmetric catalysts in the saponification of mandelic acid esters, although the rate effects and optical yields were small.<sup>14</sup> The cycloamyloses catalyze the decarboxylation of substituted cyanoacetic acids, accelerations of up to 15-fold being observed.<sup>15</sup> In neither of these studies was the relationship between complexing and catalysis determined. Cycloheptaamylose was found to inhibit the basic hydrolysis of ethyl *p*-aminobenzoate, the complexed ester being completely unreactive (within experimental error) in 0.04 *N* barium hydroxide solution.<sup>16</sup> The extent of inhibition due to added cycloheptaamylose was consistent with the formation of a 1:1 complex<sup>17</sup> having a dissociation constant of  $2.34 \times 10^{-3}$  *M*. Most pertinent to the present investigation is the work of Hennrich and Cramer where it was found that the cycloamyloses accelerate the decomposition of diaryl phosphates in heterogeneous alkaline mixtures with concomitant phosphorylation of the amylose.<sup>18</sup> The acceleration of the release of phenol from di-*p*-chlorophenyl pyrophosphate was *ca.* 200-fold with cycloheptaamylose, smaller accelerations being observed with cyclohexaamylose and cyclooctaamylose. Furthermore, the acceleration was reduced when phenolic products were present in the reaction mixture. Unfortunately, limitations of the experimental system made it impossible to investigate the relationship between the stability of the complex and its reactivity. The relative importance of steric and electronic effects on reactivity and on complexation could not be determined. The present investigation of the effects of cycloamyloses on the alkaline hydrolysis reactions of phenyl esters was therefore undertaken in an effort to determine these critically important facts.

## Experimental Section

Cycloamyloses were initially obtained as a gift from Professor Dexter French. Subsequently cyclohexaamylose was purchased from Applied Science Laboratories. At the present time both

cyclohexaamylose and cycloheptaamylose are available from Pierce Chemical Co. (Rockford, Ill.). Cyclooctaamylose was obtained as the pure crystalline material from Professor French. Cycloheptaamylose was purified by recrystallization from water and dried at 110° for 12 hr. *Anal.* Calcd for  $C_{42}H_{70}O_{38}$ : C, 44.44; H, 6.22. Found: C, 44.11; H, 6.29.

Cyclohexaamylose was purified by recrystallization from 1-propanol-water<sup>7</sup> followed by recrystallization from water and drying under vacuum at 80° for 12 hr. *Anal.* Calcd for  $C_{36}H_{56}O_{30}$ : C, 44.44; H, 6.22. Found: C, 44.16, 44.44; H, 6.32, 6.35.

Both the cyclohexaamylose and cycloheptaamylose were found to be pure and free from cross-contamination as judged by paper chromatography on Whatman No. 1 paper (descending chromatography, 25°, solvent: 1-butanol-dimethylformamide-water, 2:1:1, v/v/v) using 1% alcoholic iodine as a developing spray. The *R<sub>f</sub>* values of cyclohexa- and -heptaamylose were 0.23 and 0.20, respectively.

The specific rotation of aqueous cyclohexaamylose was  $[\alpha]^{25}_D$  150.2 ± 4.20° (concentration varied from 0.0104 to 0.0286 g/ml), in agreement with the literature value<sup>19</sup> of 150.5 ± 0.5°. No trend was observed in the specific rotation values as the cyclohexaamylose concentration was varied. A Rudolph Model 200S/655 manual photoelectric spectropolarimeter equipped with an electrical null reading device was used to determine the optical rotations.

The molecular weight of cyclohexaamylose in water at 37° was determined using a Mechrolab Model 301A vapor pressure osmometer with sucrose as a standard. Three samples at concentrations of 58, 132, and 50 g/l. gave molecular weights of 1120, 1090, and 1110, respectively (calculated 972). Since raffinose pentahydrate also gave a somewhat high value of 630 (calculated 594), it is possible that there is some systematic error involved; hydration of the cycloamylose would also lead to high observed values. Both the molecular weight data and the optical rotation data indicate that in aqueous solution cyclohexaamylose is only slightly associated (if at all).

**Esters.** Phenyl acetates were purchased from commercial sources (Distillation Products Industries or Aldrich Organic Chem. Co.) or were synthesized generally by the method of Spasov.<sup>20</sup> The physical properties of the esters prepared as well as the wavelengths used to follow the reactions are shown in Table I. *m*-Carboxy-

Table I. Phenyl Acetates Used as Substrates

Acetate	Bp, °C (mm), or mp, °C	Wavelength, <sup>a</sup> mμ
3,5-Dimethylphenyl	143 (54)	295
3,4,5-Trimethylphenyl	58.5–59.5	285–300
<i>m</i> -Ethylphenyl	127.5 (31)	280–298
<i>m</i> - <i>t</i> -Butylphenyl	160–161 (61)	290–295
<i>p</i> - <i>t</i> -Butylphenyl	157 (50)	300
<i>p</i> -Methoxyphenyl	160 (55)	315
<i>p</i> -Bromophenyl	154 (45)	305
<i>m</i> -Chlorophenyl	105–109 (15–16)	299–305
<i>p</i> -Chlorophenyl	143 (55)	305
<i>p</i> -Cyanophenyl	56–57	290
<i>m</i> -Carboxyphenyl	131–132.5	330
<i>p</i> -Carboxyphenyl	191–192.5	280–308

<sup>a</sup> Phenyl acetate and the tolyl acetates were assayed at 298–305 mμ, *m*-nitrophenyl acetate at 390 mμ, *p*-nitrophenyl acetate at 400 mμ, and *o*-nitrophenyl acetate at 470 mμ. (These wavelengths proved to be experimentally convenient but are not necessarily optimal.)

phenyl acetate was prepared by reaction of acetic anhydride with *m*-carboxyphenol in pyridine followed by recrystallization from chloroform. *p*-Carboxyphenyl acetate was synthesized by the method of Renison and Huls<sup>21</sup> and recrystallized from chloroform. *p*-Carboxyphenyl 2-methylpropionate was prepared in 10% yield by reaction of *p*-carboxyphenol with isobutyryl chloride in pyridine followed by recrystallization from chloroform, mp 181.5–183°. *Anal.* Calcd for  $C_{11}H_{14}O_4$ : C, 63.46; H, 5.77. Found: C,

63.17; H, 5.85. *p*-Carboxyphenyl 3,3-dimethylbutyrate was prepared in 25% yield by reaction of *p*-carboxyphenol with *t*-butylacetyl chloride (Aldrich Chemical Co.) in pyridine followed by recrystallization from chloroform, mp 195–197°. *Anal.* Calcd for  $C_{17}H_{20}O_4$ : C, 66.10; H, 6.78. Found: C, 65.86; H, 6.72. Reactions of this and the previous compound were followed at 280 m $\mu$ .

**Kinetics of Hydrolysis of Phenyl Acetates.** The reactions were carried out by following the appearance of phenol spectrophotometrically using a Cary Model 14 recording spectrophotometer equipped with a thermostated cell compartment, thermostated cell holder, and 0–1 and 0–0.1 absorbance slide wires. The reaction medium, generally 3.00 ml of pH 10.6 sodium carbonate buffer, was placed in a stoppered 1-cm silica cell and thermostated for 15 min. The reaction was initiated by the addition of 15  $\mu$ l of a stock solution of the ester in acetonitrile (Eastman Spectro Grade) using a plastic flat-tipped stirring rod (Calbiochem). The final ester concentration was  $1 \times 10^{-4}$  M and the acetonitrile concentration was 0.5% (v/v). When fast reactions were being followed, the time necessary to complete the mixing of the reactants and begin recording the spectral changes did not exceed 6 sec. The pH determined using a Radiometer 4c pH meter did not change during the course of the reaction. The hydrolysis of the phenyl acetates as determined in these buffered alkaline solutions followed (pseudo) first-order kinetics. Times were determined from the recorded chart divisions by calibration using a Precision Scientific Time-It electric clock and are accurate to  $\pm 1\%$ . The infinite absorbance values were obtained after at least eight half-lives and reactions were recorded through 70% of completion. The rate constants were calculated by electronic computation of the linear least-squares slope of the line formed by the set of points [time,  $\log(\text{absorbance} - \text{infinite absorbance})$ ] and division of the slope by  $-0.4343$ . The resulting points were checked by examination of a computer-produced graph of the first-order plot in order to eliminate transcription errors. The reported rate constants are averages of two or three determinations which agreed within 3%. The spectra of the products corresponded to the spectra obtained by addition of pure phenol to the buffered cycloamylose solutions.

**Determination of Dissociation Constants by Kinetic Methods.** The observed first-order rate constants for hydrolysis of phenyl acetates (as measured by phenol release) in the absence ( $k_{\text{un}}$ ) and presence ( $k_{\text{obsd}}$ ) of added cycloamylose were determined. From 5 to 12 points were obtained at cycloamylose concentrations spanning (whenever possible) the value of  $K_{\text{dis}}$  (the dissociation constant of the cycloamylose-ester complex calculated assuming a 1:1 stoichiometry). The values of  $-K_{\text{dis}}$  and  $k_2$  (the maximal catalyzed rate due to decomposition of the fully complexed ester) were obtained as the slope and *Y* intercept of the line<sup>22,23</sup> formed by plotting  $k_{\text{obsd}} - k_{\text{un}}$  against  $(k_{\text{obsd}} - k_{\text{un}})/[\text{cycloamylose}]$ . Calculations were carried out using Eadie-type plots rather than the Lineweaver-Burk plot previously used<sup>3</sup> because the Eadie plot is statistically preferable.<sup>24</sup> The slope and intercept were obtained by electronic computation of the least-squares line. This appeared adequate since in an Eadie plot it is relatively easy to choose concentrations so that the experimental points are evenly distributed along the line. Unlike the usual situation in enzyme kinetics, the cycloamylose here is present in large excess over the substrate concentration and may be accurately determined by weight. The range of cycloamylose concentrations (depending on the value of  $K_{\text{dis}}$ ) varied from  $6 \times 10^{-4}$  to  $4 \times 10^{-3}$  M. The error limits of  $K_{\text{dis}}$  were calculated from the experimental data by application of Student's *t* test for 95% probability of fit to the least-square line. The error in  $k_2$  may be expected to parallel the error in  $K_{\text{dis}}$ . Graphical estimates of error limits made by drawing extreme lines through Lineweaver-Burk plots were significantly less than the computed values shown in Table IV.

**Determination of Dissociation Constant by Spectrophotometric Methods.** The increase in absorbance of the aromatic chromophore in the presence of varying amounts of cycloamylose were determined using a Cary Model 14 recording spectrophotometer equipped with a thermostated cell compartment and a 0–0.1, 0.1–0.2 slide wire. To minimize hydrolysis of esters and suppress phenol ionization a pH 2.2 hydrochloric acid-potassium chloride buffer ( $I = 0.06$ ) was employed. Since the cycloamyloses are relatively unstable in acid solution the solutions were used within 1 hr

of preparation. The substrate concentration was held constant at  $10^{-4}$  M. The reference compartment contained phenol or ester and cycloamylose solutions contained in separate 1-cm silica cells. The sample compartment contained a cell with buffer and a cell with combined cycloamylose and phenol or ester. The difference spectrum of  $4.4 \times 10^{-3}$  M glucose plus  $5.8 \times 10^{-4}$  M phenol  $\alpha$  phenol was identical with the difference spectrum of phenol  $\alpha$  phenol.

In order to calculate the cycloamylose-substrate dissociation constants a linear relationship was employed<sup>25</sup> relating the observed spectral changes to the added concentrations of cycloamylose and ester (see Appendix). The slope  $1/\Delta\epsilon$  and the intercept  $K_{\text{dis}}/\Delta\epsilon$  were obtained by electronic computation of the linear least-squares line through the experimental points. The validity of the method of data treatment was checked by using synthetic data available in<sup>26</sup> the literature as well as by redetermining the dissociation constant of the methyl orange-cyclohexaamylose complex (see footnotes *d* and *e* to Table VI).

**Determination of Inhibition Constants.** The dissociation constants of cycloamylose-inhibitor complexes ( $K_i$ ) were determined by measuring the rate of *m*-nitrophenyl acetate hydrolysis in the presence of a fixed amount of cycloamylose and varying concentrations of added inhibitor. The concentration of the ester was  $9.9 \times 10^{-3}$  M and the cycloamylose was  $3.6 \times 10^{-3}$  M; the inhibitor concentrations were chosen, when possible, to span the value of  $K_i$ .

One milliliter of  $1.08 \times 10^{-3}$  M cycloamylose solution in pH 10.05 sodium carbonate buffer was mixed with 2 ml of a sodium carbonate buffer solution of the inhibitor, the pH was adjusted if necessary to 10.05, and the mixture in a 1-cm quartz cell was thermostated for 15 min at  $25.0 \pm 0.1^\circ$  in a Cary Model 14 spectrophotometer. The ester was added in 15  $\mu$ l of acetonitrile (Eastman Spectro Grade) and the appearance of phenoxide ion was followed at 390 m $\mu$ .

Added inhibitor at the highest concentrations used had only small effects on the rate of the uncatalyzed reaction. The pH of the reaction mixture did not vary by more than 0.04 unit during the course of the reaction. The values of  $k_2$  and  $K_{\text{dis}}$  for the cycloamylose-catalyzed decomposition of *m*-nitrophenyl acetate were previously determined (Table IV). The inhibitor concentration  $[I]$  was plotted as a function of  $(k_2 - k_{\text{obsd}})/(k_{\text{obsd}} - k_{\text{un}})$ . The *Y* intercept is  $-K_i$  and the slope is  $[\text{cycloamylose}] \times K_i/K_{\text{dis}}$  (see Appendix). A sample plot is shown in Figure 5.

## Results

**Kinetics of Hydrolysis of Phenyl Acetates in the Presence of Glucose and Methyl Glucoside.** The pseudo-first-order rate constants for the alkaline hydrolysis of a variety of substituted phenyl acetates are shown in Table II. The hydroxide ion reaction rates vary in the manner expected from the electronic character of the substituents. Data for the various *meta*- and *para*-substituted phenyl acetate hydrolysis rates gives an excellent fit to a Hammett-type relationship. The line formed by plotting  $\log(k/k_H)$  vs. the substituent constant<sup>27</sup>  $\sigma^+$  gives a slightly better correlation coefficient than the corresponding plot using ordinary  $\sigma$  values (footnote *c* to Table II), indicating that there is not a significant charge delocalization in the aromatic ring in the transition state.

No unusual effects are observed when 0.06 M  $\alpha$ -methyl glucoside is added to the reaction mixture, there being only a 10–20% acceleration of the hydrolysis rates (Table II). Addition of 0.06 M glucose to the reaction mixture causes a two- to threefold increase in the hydrolysis rates. The larger effect due to glucose is presumably the result of reaction with the hemiacetal

<sup>a</sup> Pseudo-first-order rate constants obtained using pH 10.60 sodium carbonate buffer with 0.5% (v/v) acetonitrile added; [ester]  $\approx 1 \times 10^{-4}$  M. <sup>b</sup> Taken from ref 27. <sup>c</sup> The correlation coefficients obtained for the least-squares fit to the line formed by plotting  $\log(k/k_H)$  vs.  $\sigma$  for the uncatalyzed, methyl glucoside, and glucose reaction mixtures were 0.972, 0.977, and 0.980; for the plot vs.  $\sigma^+$  they were 0.987, 0.989, and 0.992, respectively. The  $\rho$  values obtained for the three reaction systems using  $\sigma^+$  values were 1.10, 1.07, and 1.24.

alkoxide ion derived from glucose. This is consistent with the fact that the Hammett  $\rho$  value for the glucose-catalyzed reaction is 1.24 as compared with 1.10 for the pure hydroxide ion reaction (Table II). The alkoxide ion derived from glucose is more sensitive than hydroxide ion to the electronic nature of the substituted carbonyl group.

**Kinetics of Hydrolysis of Phenyl Acetates in the Presence of Cycloamyloses.** The hydrolysis rates of a variety of substituted phenyl esters in the absence ( $k_{un}$ ) and presence ( $k_{obsd}$ ) of 0.01 M added cycloamyloses are shown in Table III. Depending on the structure of

Figure 1. Graph of the logarithm of the acceleration of the rate of phenol release due to  $1 \times 10^{-3}$  M cycloamylose vs. the Hammett substituent constant  $\sigma$ : ●, added cycloheptaamylose; ○, added cyclohexaamylose (for experimental conditions see Table III).

chlorophenyl acetate occurs 113 times more rapidly in the presence of 0.01 M cyclohexaamylose. The acceleration  $k_{obsd}/k_{un}$  bears no apparent relationship to the electronic character of the substituents. A Hammett-type plot of  $\log(k_{obsd}/k_{un})$  vs. the substituent constant  $\sigma$  shows a tremendous scatter (Figure 1).

<sup>a</sup> The pseudo-first-order rate constants were determined by following the release of phenol spectrophotometrically: see Experimental Section. All determinations were done at  $25.0 \pm 0.2^\circ$  using pH 10.60 sodium carbonate buffer,  $I = 0.2$ , with 0.5% (v/v) added acetonitrile.

the ester, marked accelerations of the phenol release may occur as the result of addition of the cycloamyloses to the reaction mixture. Thus, *m*-*t*-butylphenyl acetate hydrolyzes 240 times more rapidly in the presence of 0.01 M cycloheptaamylose, and the hydrolysis of *m*-

However, there does appear to be a relationship between the stereochemistry of substitution of the phenyl acetates and the degree of acceleration of the hydrolysis reaction. Figure 1 suggests that phenyl acetates having substituents in the position *meta* to the acetoxy group

Figure 2. The pseudo-first-order rate constant for release of phenol from *p*-nitrophenyl acetate at pH 10.6 plotted as a function of added cycloheptaamylose; 0.5% (v/v) acetonitrile-water, 25°, [*p*-nitrophenyl acetate]  $\approx 1 \times 10^{-4}$  M.

Figure 3.  $1/(k_{\text{obs}} - k_{\text{un}})$  for *p*-nitrophenyl acetate decomposition is plotted vs. the reciprocal of the cycloheptaamylose concentration (data from Figure 2).

exhibit the largest rate accelerations. For example, although *m*-chlorophenyl acetate hydrolysis shows a 113-fold acceleration in the presence of cyclohexaamylose, the *para* isomer shows only a threefold acceleration; likewise *m*-*t*-butylphenyl acetate shows a 230-fold acceleration whereas the *para* isomer shows only a 1.7-fold rate enhancement. Similar observations may be made for the effects of added cycloheptaamylose on reaction of substituted phenyl acetates, there being a remarkable stereoselective enhancement of the phenol release reaction favoring the *meta*-substituted compounds.

Because the cycloamyloses form inclusion complexes in solution with a variety of organic and inorganic substances<sup>6-9</sup> it appeared likely that the rate increases shown in the data of Table III involved a cycloamylose-ester complex. Such being the case, it is uncertain whether the apparent geometric specificity evident in the accelerations is due to differences in the reactivity of the complexes (or in both). In an effort to resolve this problem the concentration dependence of the catalytic action was examined. The effect of varying (excess) cycloheptaamylose concentration on the pseudo-first-order rate constant for *p*-nitrophenyl acetate hydrolysis (as measured by phenol release) is shown in Figure 2. The rate accelerations approach a

Figure 4.  $(k_{\text{obs}} - k_{\text{un}})$  for *p*-nitrophenyl acetate decomposition is plotted as a function of  $(k_{\text{obs}} - k_{\text{un}})/[\text{cycloheptaamylose}]$  (data from Figure 2).

maximum saturation value similar to the behavior observed in enzyme kinetics. The data were treated by a variant of Michaelis-Menten kinetics previously employed for investigation of reactions involving complex formation. By plotting the *p*-nitrophenyl acetate data in the form of  $1/(k_{\text{obs}} - k_{\text{un}})$  vs. the reciprocal of the cycloamylose concentration a straight line is obtained (Figure 3) having a slope of  $K_{\text{dis}}/k_2$  and a *Y* intercept equal to  $1/k_2$ , where  $K_{\text{dis}}$  is the dissociation constant of the complex and  $k_2$  is the rate constant for reaction of the entirely complexed ester ( $k_{\text{obs}} - k_{\text{un}}$  at infinite cycloamylose concentration).<sup>28</sup>

In order to permit a more accurate evaluation of the various values of  $K_{\text{dis}}$  and  $k_2$ , a statistically preferable form<sup>24</sup> of Michaelis-Menten kinetics due to Eadie<sup>25</sup> was employed. As shown in Figure 4 for the *p*-nitrophenyl acetate data, by plotting  $k_{\text{obs}} - k_{\text{un}}$  against  $(k_{\text{obs}} - k_{\text{un}})/[\text{cycloamylose}]$  a straight line is obtained with slope  $-K_{\text{dis}}$  and a *Y* intercept of  $k_2$ .

Dissociation constants and maximal rate accelerations obtained in this manner (by electronic computation; see Experimental Section) are presented in Table IV. It is of importance to compare the dissociation constants and the rate effects observed with some of the isomeric phenyl acetates. *p*-Nitrophenyl acetate forms a more stable complex with both cyclohexaamylose and cycloheptaamylose than does *m*-nitrophenyl acetate, but the maximal rate accelerations  $k_2/k_{\text{un}}$  are much greater for the *meta* isomer. Similarly, although the stability of the *m*-*t*-butylphenyl acetate-cyclohexaamylose complex differs by only a factor of 3 from that of the *para* isomer, the release of phenol from the *meta* isomer is accelerated some 230 times more than from the *para* isomer. Qualitatively similar observations may be made for the reaction of *o*-, *m*-, and *p*-tolyl acetates in the presence of cyclohexaamylose. Thus, the

(28) This method of data treatment is in effect the Lineweaver-Burk plot of  $1/\text{velocity}$  vs.  $1/\text{substrate concentration}$  which is frequently employed in studies of the kinetics of enzyme-catalyzed reactions: B. Lineweaver and D. Burk, *J. Am. Chem. Soc.*, **56**, 658 (1934).

<sup>a</sup> In pH 10.60 carbonate buffer,  $I = 0.2$ , 0.5% acetonitrile-water unless otherwise noted. All determinations at  $25.0 \pm 0.1^\circ$ . Error limits for  $K_{dis}$  were calculated from the experimental data by application of Student's *t* test at the 95% probability level. The error in  $k_s$  may be expected to parallel the error in  $K_{dis}$ . <sup>b</sup> In pH 10.01 carbonate buffer,  $I = 0.2$ , 0.5% acetonitrile-water. <sup>c</sup> Determined by graphically titimating the cycloheptaamylose concentration necessary to result in the half-maximal velocity from a plot of  $k_{obs}$  vs. [cycloheptaamylose]; [ester]  $\approx 2 \times 10^{-3} M$ . <sup>d</sup> In pH 10.01 carbonate buffer,  $I = 2.0$  (by addition of potassium chloride). 0.5% acetonitrile-water. <sup>e</sup> In pH 10.58 carbonate buffer,  $I = 0.2$ , 10% (v/v) (1.9 *M*) acetonitrile-water.

tereospecific rate accelerations are unrelated to the strength of binding. The sensitivity of  $k_s$  to the stereochemistry of the substrate is strikingly similar to enzyme-catalyzed reactions (see Discussion).

**Competitive Inhibition of Cycloamylose Catalysis.** In order to determine the stability of complexes of the cycloamyloses with a variety of unreactive molecules as well as to provide further information about the nature of the reactive complex, the competitive inhibition of the cyclohexaamylose-catalyzed decomposition reaction of *m*-nitrophenyl acetate was examined. As anticipated, the rate effects of the cycloamyloses were decreased upon addition of a variety of organic compounds to the reaction mixture. By determining the extent of inhibition as a function of added inhibitor concentration it was possible to obtain an inhibition constant  $K_i$  which is the dissociation constant of the cycloamylose-inhibitor complex (see Experimental Section). The treatment of the data is exemplified by Figure 5. Application of this method made possible the determination of the inhibition constants for the anions shown in Table V. From these data it is apparent that small anions such as acetate and propionate do not bind well to cyclohexaamylose. Anions derived from acids containing larger relatively hydrophobic groups such as adamantane or cyclohexane form relatively stable complexes (see Discussion).

**Determination of Cycloamylose-Substrate Dissociation Constants by Spectrophotometric Methods.** The formation of inclusion complexes with cycloamyloses is known to lead to perturbations of the ultraviolet spectra of a variety of organic molecules ranging from organic dyes<sup>29</sup> such as marine blue, methyl orange, and crystal violet to compounds such as *N*-acetyltyrosine ethyl ester.<sup>30</sup> Thus, it appeared possible to observe significant

<sup>a</sup> All determinations were made at  $25.0 \pm 0.1^\circ$  using pH 10.0 sodium carbonate buffer,  $I = 0.2$  (but when  $K_i$  was  $>10^{-2} M$  then  $I > 0.2$ ), 0.5% acetonitrile. <sup>b</sup> No unusual effects are observed with cationic inhibitors; for example, tetraethylammonium bromide gives  $K_i = 3.3 \pm 0.6 \times 10^{-3} M$ . <sup>c</sup> Calculated assuming a 1:1 stoichiometry in the complex; it is possible that molecules such as *p*-benzoylbenzoate form higher order complexes, as has been observed for methyl orange<sup>17</sup> (where the dissociation constants differ by  $\sim 10^5$ ). The error limits were obtained by drawing extreme lines through the experimental points. <sup>d</sup>  $K_i$  for inhibition of cycloheptaamylose catalysis is  $7 \pm 4 \times 10^{-4} M$ .

changes in the ultraviolet absorption spectra of aromatic molecules related to ester substrates occurring as the result of complex formation. This was indeed the case. An example of the type of observed spectral change is shown in Figure 6. Addition of  $2.5 \times 10^{-2} M$  cyclohexaamylose to an aqueous solution of  $1 \times 10^{-4} M$  *p*-*t*-butylphenol causes a spectral change almost identical with that observed when the phenol is dissolved in dioxane instead of water. This result is similar to observations made for cycloamylose complexes of iodine<sup>8</sup> and *N*-acetyltyrosine ethyl ester.<sup>8,30</sup> Glucose, at these concentration levels, has no significant effect on the ultraviolet spectrum. The similarity of the aqueous cyclohexaamylose solution spectrum to the

Figure 5. Added inhibitor concentration  $[I]$  graphed as a function of  $(k_2 - k_{\text{obs}})/(k_{\text{obs}} - k_u)$  for inhibition by *p*-chlorocinnamate ion of the acceleration of *m*-nitrophenyl acetate decomposition by cyclohexaamylose (experimental conditions given in Table V).

Figure 6. Ultraviolet absorption spectrum of *p*-*t*-butylphenol in various solvents (the absorbance values are arbitrarily shifted vertically for purposes of clarity);  $[\text{cyclohexaamylose}] = 2.5 \times 10^{-3} \text{ M}$ ;  $[\text{phenol}] \approx 1 \times 10^{-4} \text{ M}$ .

dioxane solution spectrum suggests that the aromatic chromophore is largely included in the cycloamylose cavity (see Discussion).

The absorbancy changes resulting from the addition of varying amounts of cycloamyloses to the aqueous solutions of the substrates were treated by plotting<sup>19</sup>  $[A][B]/\Delta Abs$  against  $[A] + [S]$ , where  $[A]$  and  $[S]$  are the initial stoichiometric concentrations of cycloamylose and substrate and  $\Delta Abs$  is the spectral perturbation observed as the difference spectrum. Under the experimental conditions employed the product  $[A][S]$  was maintained much larger than  $[C]^2$  where  $[C]$  is the concentration of the complex. Examples of such determinations are shown in Figure 7. The dissociation constants of some cyclohexaamylose complexes determined in this manner are shown in Table VI. Of greatest interest is the agreement between dissociation constants obtained by spectrophotometric, kinetic, and inhibition methods. For *m*-chlorophenyl acetate the

Figure 7. Determination of cyclohexaamylose-substrate dissociation constants by spectrophotometric methods by plotting  $([\text{cyclohexaamylose}][\text{ester}])/\text{absorbance}$  as a function of  $[\text{cyclohexaamylose}] + [\text{ester}]$ ; experimental conditions are given in Table VI.

Table VI. Dissociation Constants of Cyclohexaamylose Complexes Determined by Spectrophotometric Methods<sup>a</sup>

Substrate	Wavelength, $m\mu^b$	$K_{\text{obs}}$ , $M$
Phenol	273, 280	$5.3 \times 10^{-3}$
3,5-Dimethylphenol	235, 280	$1.6 \times 10^{-3}$
3,5-Dimethylphenyl acetate	235	$1.3 \times 10^{-3}$
<i>m</i> -Chlorophenyl acetate	230, 235	$4.7 \times 10^{-3}$
<i>p</i> -Chlorophenyl acetate	269, 276	$1.6 \times 10^{-3}$
<i>m</i> - <i>t</i> -Butylphenol	230, 282	$3.4 \times 10^{-3}$
<i>p</i> - <i>t</i> -Butylphenol	278, 285	$1.2 \times 10^{-3}$
2-Naphthol	290, 335	$3.1 \times 10^{-3}$
<i>p</i> -Chlorocinnamate <sup>c</sup>	290, 301	$5.1 \times 10^{-3}$
Methyl orange <sup>d,e</sup>	510, 520	$2.2 \times 10^{-4}$

<sup>a</sup> Determined using pH 2.2 potassium chloride-hydrochloric acid buffer,  $I = 0.06$  unless otherwise noted. All determinations were made at  $25.0 \pm 0.1^\circ$ . <sup>b</sup> Where more than one wavelength is listed the reported dissociation constant is the average of two determinations which agreed to within 10%. <sup>c</sup> Determined using pH 10.05 sodium carbonate buffer,  $I = 0.2$ . <sup>d</sup> Determined using pH 6.71, 0.1 *M* sodium and potassium phosphate buffer. At cyclohexaamylose concentrations  $> 5 \times 10^{-4} \text{ M}$ , additional spectral perturbations began to appear suggesting the formation of higher order complexes having a much larger dissociation constant; see also ref 17. <sup>e</sup> Reported  $1.12 \times 10^{-4} \text{ M}$ : W. Broser and W. Lautsch *Z. Naturforsch.*, **8b**, 711 (1953).

comparable values are  $5.6 \times 10^{-3} \text{ M}$  (kinetic) and  $4.7 \times 10^{-3} \text{ M}$  (spectral), while for 3,5-dimethylphenyl acetate they are  $1.5 \times 10^{-3} \text{ M}$  and  $1.3 \times 10^{-3} \text{ M}$ , respectively.<sup>11</sup> The spectrophotometric and competitive inhibition methods give the same value for the dissociation constant of the cyclohexaamylose complex of *p*-chlorocinnamate ion.

**Temperature Dependence of Cyclohexaamylose-Substrate Dissociation Constants.** The kinetic dissociation constants of some cyclohexaamylose-substrate complexes were determined at temperatures between 15 and  $55^\circ$  and the experimental results are shown in Table VII. In order to calculate the thermodynamic changes accompanying the dissociation process the least-squares slope was computed of the line formed by plotting  $\ln K_{\text{obs}}$  against the reciprocal of the absolute temperature (Figure 8). From the relationship  $d(\ln K_{\text{eq}})/d(1/T) = -\Delta H^\circ/R$  and the assumption that

(31) 2-Naphthol forms a relatively stable complex with cyclohexaamylose ( $K_{\text{obs}} = 3.1 \times 10^{-3} \text{ M}$ ) although an azo dye with a 2,8-disubstituted naphthol group apparently does not.<sup>17</sup>

Figure 8. Plot of  $\ln K_{diss}$  vs. the reciprocal of the absolute temperature. The data is that of Table VII for dissociation of cycloheptaamylose-substrate complexes:  $\bullet$ , *m*-ethylphenyl acetate;  $\square$ , *m*-lorophenyl acetate;  $\blacklozenge$ , 3,4,5-trimethylphenyl acetate.

Table VII. Temperature Dependence of Some Cycloheptaamylose-Substrate Dissociation Constants<sup>a</sup>

Estor	Temp, °C	$K_{diss}^b$ $10^{-3} M$
<i>m</i> -Chlorophenyl acetate	15.3	$3.2 \pm 0.7$
	25.0	$3.5 \pm 0.9^c$
	34.8	$4.0 \pm 0.4$
	45.1	$3.5 \pm 0.5$
	55.0	$4.3 \pm 1.0$
3,4,5-Trimethylphenyl acetate	25.0	$5.0 \pm 1.1$
	25.1	$4.7 \pm 0.6$
	34.8	$6.2 \pm 0.4$
	45.3	$5.8 \pm 0.4$
	47.1	$6.4 \pm 1.7$
<i>m</i> -Ethylphenyl acetate	55.0	$7.8 \pm 0.3$
	18.8	$2.00 \pm 0.44$
	25.0	$2.16 \pm 0.36$
	32.8	$2.74 \pm 0.56$
	41.1	$2.85 \pm 0.37$
	48.2	$3.70 \pm 0.53$
	54.2	$4.97 \pm 0.68$

<sup>a</sup> At pH 10.01 (25°),  $I = 0.2$  sodium carbonate buffer with 0.5% tonitrile-water unless otherwise noted. <sup>b</sup> Error limits computed in the experimental data by application of Student's *t* test at the % probability level. <sup>c</sup> At pH 10.60 (25°), other conditions as in *a*.

heat capacities of reactants and products are not significantly different (entirely justified here since the average error in  $K_{diss}$  is ~20%) one obtains the enthalpy change  $\Delta H^\circ = -R(\text{slope})$  and  $\Delta S^\circ = R(\text{intercept})$ . The computed line was used to calculate an average value of  $\Delta F^\circ_{298}$ .

#### Discussion

The cycloamyloses cause a markedly stereoselective acceleration of the phenol release from substituted phenyl acetates in alkaline solution. Unlike methyl glucoside or glucose, which produces small, uniform rate

Figure 9. Scale molecular models of cyclohexaamylose complexes: (A) *m*-*t*-butylphenyl acetate complex with the *t*-butyl group inserted into the cavity from the secondary hydroxyl side; (B) *p*-*t*-butylphenyl acetate complex constructed as in A; (C) *p*-*t*-butylphenyl acetate complex constructed by inserting the acetyl group through the cavity until it protrudes from the primary hydroxyl side of the cyclohexaamylose; (D) adamantanecarboxylic acid complex. The oxygen and hydrogen atoms of the guest molecule are coated with metallic paint for greater contrast (the slots in the oxygen atoms are for hydrogen bonds).<sup>32</sup>

effects, both cyclohexaamylose and cycloheptaamylose cause large, nonuniform effects, the rate of phenol release from *meta*-substituted phenyl acetates being greatly enhanced whereas phenol release from the corresponding *para* isomers is only slightly enhanced. The rate effects due to cyclooctaamylose are also large but are much less stereoselective. The stereoselectivity is exerted independently of the stability of the complex and is thus similar to observations made for enzyme-catalyzed reactions (see introductory section). The cycloamylose system also shows spectral changes on binding, competitive inhibition, nonproductive binding, and saturation of the substrate with cycloamylose.<sup>33</sup> A minimal reaction scheme which accommodates these facts is shown below. Here, cycloamylose (CA) and

ester (S) undergo a reversible association to form a cycloamylose-substrate complex  $[\text{CA} \cdot \text{S}]$  which may undergo a reaction with rate constant  $k_2$  to form phenol  $\text{P}_1$  and product(s)<sup>31</sup>  $\text{CA} \cdot \text{P}_2$ . The cycloamylose

(32) For an example of the saturation of a substrate with an enzyme see F. J. Kézdy and M. L. Bender, *Biochemistry*, **1**, 1097 (1962).

(33) Accompanying article: R. L. VanEtt, G. A. Clowes, J. F. Sebastian, and M. L. Bender, *J. Am. Chem. Soc.*, **89**, 3253 (1967).

may also undergo a reversible association with an inhibitor I to form a cycloamylose-inhibitor complex [CA·I]. Except with sterically hindered or strongly solvated molecules the reversible association to form a 1:1 complex with cycloamyloses may be expected to be rapid compared<sup>17</sup> to the rates of chemical reactions described here.

The catalytic activity of enzymes is localized in an area termed the active site which is responsible for the binding of substrates, coenzymes, and inhibitors, and is responsible for catalyzing the chemical transformations.<sup>34</sup> The cycloamylose system developed here is an interesting model for an enzyme active site in that its properties are completely explained by considering the region of the cycloamylose cavity and the secondary hydroxyl<sup>35</sup> groups to be the active site of the cycloamylose torus. Most importantly, such a model readily explains the stereoselective rate accelerations. A scale<sup>36</sup> molecular model of a complex of *m-t*-butylphenyl acetate with cyclohexaamylose is shown in Figure 9A. This model was constructed by inserting the hydrophobic *t*-butyl group into the cycloamylose cavity from the secondary hydroxyl side.<sup>36</sup> This results in fixing the position of the ester function in close proximity to the secondary hydroxyl groups. A striking difference is seen in models of cyclohexaamylose complexes of *p-t*-butylphenyl acetate. If the *t*-butyl group is inserted first into the secondary side, then the ester function is located at some distance from the hydroxyl groups (Figure 9B). However, if the acetyl portion is inserted into the cavity from the secondary side until it protrudes from the primary hydroxyl side (which cannot be done for the *meta* isomer), then the aromatic ring and most of the *t*-butyl group are included in the cycloamylose cavity (Figure 9C). The ester function may be partially shielded from nucleophilic attack by hydroxide ion in solution, which would be consistent with the fact that the basic hydrolysis of ethyl *p*-aminobenzoate is inhibited by complexation with cycloheptaamylose.<sup>16</sup> In this model the ester function is located in close proximity to the primary hydroxyl groups. This model together with the unreactivity of the *para* isomer suggests that the interaction which leads to increases in the rate of phenol release involves the secondary hydroxyl groups; this has, in fact, been established.<sup>23</sup>

These models of the cycloamylose-substrate complexes also explain why spectral changes may be observed when some organic substrates form cycloamylose complexes. In cyclohexaamylose complexes, the aromatic chromophore of *m-t*-butylphenyl acetate is not greatly removed from the aqueous environment (Figure 9A); the model is thus consistent with the fact that the spectrum of *m-t*-butylphenol plus cyclohexaamylose in

water shows only a small spectral perturbation compared to the spectrum of the phenol in water. However, *p-t*-butylphenol plus cyclohexaamylose shows a marked spectral change resembling the spectrum of the phenol in dioxane solution (Figure 6); this perturbation is consistent with the inclusion of the aromatic chromophore in the ether-like cycloamylose cavity. These arguments indicate that *p-t*-butylphenyl acetate is probably included in the cycloamylose active site with the ester function near the primary hydroxyl groups and the *t*-butyl group near the secondary hydroxyl groups, as shown in Figure 9C.

Differences are observed in the stereoselectivity of cyclooctaamylose and the two smaller amyloses (Table III). These differences are also seen in the values of  $K_{\text{diss}}$  and  $k_2$  for cyclooctaamylose-accelerated reactions of *t*-butylphenyl acetate as seen in Table VIII. The selectivity ratio (*meta* rate acceleration/*para* rate acceleration) for *t*-butylphenyl acetate hydrolysis in the presence of cyclohexaamylose is 240 (Table IV) while with cyclooctaamylose it is only 1.7 (Table VIII). This is readily explained on consideration of the size of the respective active sites of the amyloses. In sharp contrast to cyclohexaamylose, the cyclooctaamylose cavity is so large that the *t*-butyl group of *para-t*-butylphenyl acetate may be placed in the cavity and the ester function may still be moved freely so as to orient it adjacent to the secondary hydroxyl groups. Since the cyclohexaamylose cavity is the smallest and most restrictive of the three it might be expected to be the most sensitive to the size of *para* substituents which prevent aromatic substrates from tipping in the cavity so as to orient the ester function in proximity to the secondary hydroxyl groups. This is in agreement with the observation that in the hydrolysis of *p*-nitrophenyl acetate, the maximal rate effect due to cyclohexaamylose is 3.4 while the effect due to cycloheptaamylose is 9.1 (Table IV). If there is no substituent on the phenyl ring then the acceleration due to cyclohexaamylose rises to 27 (Table IV). Thus the specificities exhibited by the *para*-substituted esters are negative specificities.

Table VIII. Maximal Rate Accelerations and Dissociation Constants for Cyclooctaamylose Complexes

Acetate substrate <sup>a</sup>	$k_2$ , sec <sup>-1</sup>	$k_2/k_{\text{un}}$	$K_{\text{diss}}$ , M
<i>m-t</i> -Butylphenyl	$4.7 \times 10^{-3}$	87	$9.9 \pm 3.6 \times 10^{-1}$
<i>p-t</i> -Butylphenyl	$3.5 \times 10^{-3}$	55	$4.0 \pm 0.7 \times 10^{-1}$

<sup>a</sup> For reaction conditions see footnote a, Table IV.

The differing rate effects which result from a change in the geometry of the active site have their parallel in enzyme chemistry. Chymotrypsin, trypsin, and subtilisin all catalyze hydrolysis reactions by similar mechanisms and yet they exhibit very different specificities.<sup>37</sup> Changes in the nature of the groups which control binding as well as in the stereochemistry of the active site readily account for differing specificities of enzymes despite seemingly identical mechanisms. Not surprisingly, enzyme-catalyzed reactions may also show

(34) A useful introductory discussion of enzyme chemistry including the active site may be found in H. R. Mahler and E. H. Cordes, "Biological Chemistry," Harper and Row, New York, N. Y., 1966, Chapter 7.

(35) The structure of cyclohexaamylose appears to be reasonably well represented by Corey-Pauling-Koltun scale molecular models [described in W. L. Koltun, *Biopolymers*, 3, 665 (1965)], since the diameter of the cavity as determined by crystallographic measurements<sup>12</sup> varies from 4.7 to 5.1 Å (measured between hydrogen atoms on C-3 of the glucose residues) while the scale model yields a distance of 5.3 Å.

(36) The secondary hydroxyl groups are on a relatively rigid carbon chain while the primary hydroxyl groups can rotate so as to partially block that part of the cavity. This further accentuates the "V" shaped nature of the cycloamylose cavity in which the open side is surrounded by the secondary hydroxyl groups.

(37) M. L. Bender and F. J. Kézdy, *Ann. Rev. Biochem.*, 34, 49 (1965); M. L. Bender and C. G. Miller, unpublished work.

ferences in reaction rates and stabilities of the enzyme-substrate complexes depending on the position of substituents on an aromatic substrate.<sup>38,39</sup> The relative inhibitory properties toward cholinesterase of a series of alkyl-substituted phenyl N-methylcarbamates<sup>39</sup> exhibit an interesting parallel with data obtained for cyclohexaamylose-catalyzed decomposition of phenyl acetates. Table IX illustrates how the seemingly unusual behavior of the enzymic system is paralleled by the cycloamylose system (it is not intended to imply that there is necessarily any actual similarity of the active sites).

Table IX. Parallel Effects of the Inhibition of Cholinesterase<sup>a</sup> on the Decomposition of Phenyl Esters in the Presence of Cyclohexaamylose

Alkyl group	Relative inhibition due to alkylphenyl N-methylcarbamates <sup>a</sup>	$k_2/K_{diss}$ for accelerations by cyclohexaamylose <sup>b</sup>
H	(1)	(1)
<i>o</i> -Methyl	1.4	0.4
<i>p</i> -Methyl	2.0	0.2
<i>m</i> -Methyl	14	3.9
3,5-Dimethyl	33	7.7
<i>m</i> -Ethyl	42	12
<i>m-t</i> -Butyl	500	64

The mechanism of inhibition of cholinesterase by substituted carbamates probably involves acylation of the enzyme [R. D. O'Brien, *et al. Med. Surg.*, 23, 117 (1965)] so that the "affinity" discussed by Metcalf and Fukuto<sup>39</sup> is probably  $k_2/K_a$  where  $k_2$  is the acylation and  $K_a$  is the dissociation constant of the cholinesterase-carbate complex. <sup>a</sup> Taken from Table IV; see footnote a.

For catalysis involving prior inclusion it is reasonable to expect that the limited number of active sites (here all presumably to the number of cycloamylose molecules) could be saturated or entirely occupied by substrate molecules.<sup>32</sup> This is in accord with the experimental data (cf. Figure 2). It is also strikingly illustrated by the fact that for the hydrolysis of *m-t*-lylphenyl acetate in the presence of cycloheptaamylose, the ester is almost completely complexed at cycloamylose concentrations greater than  $\sim 6 \times 10^{-4} M$ , usually the same hydrolysis rate constant (as measured by phenol release) being obtained even as the cycloamylose concentration is increased to  $10^{-2} M$ .

The presence of discrete catalytic sites such as in an inclusion complex also predicts that the addition of otherwise unreactive molecules to the reaction mixture might reduce the rate accelerations caused by cycloamyloses by acting as competitive inhibitors for the active site. This has been quantitatively demonstrated for the cycloamyloses, added organic molecules reducing the rate acceleration observed for release of nol from *m*-nitrophenyl acetate (Table V).<sup>40</sup> Further support for the hypothesis that the active site of the cycloamylose is the region of the cavity

and the secondary hydroxyls as well as information about the nature of forces involved in the complex may be obtained from consideration of experiments carried out with carboxyl-substituted phenyl esters. Table IV gives the maximal rate accelerations and dissociation constants determined for the reactions of *m*- and *p*-carboxyphenyl acetates in the presence of cyclohexaamylose. As previously noted, the *meta* isomer shows a large rate acceleration (68-fold) compared to the *para* isomer (fivefold). If the ester function of the *para* isomer is made increasingly hydrophobic by alkyl substitution then it is possible to bring about an inhibition of the hydrolysis reaction (Table X). This must be the result of including the ester function in the cycloamylose cavity. It was anticipated that the hydrophilic carboxylate anion would not be readily included in the cavity as a consequence of its solvation requirements. This latter hypothesis is consistent with the fact that substitution of a *p*-nitro group for the structurally similar carboxylate anion results in a 12-fold increase in the stability of the cyclohexaamylose complex (Table IV). Thus, at least two factors contribute to the formation of nonproductive complexes: steric effects and electrostatic effects.

Table X. Rate Accelerations and Dissociation Constants of Cyclohexaamylose Complexes of Carboxyl-Substituted Phenyl Esters

<i>p</i> -Carboxyphenyl ester	$k_2$ , $10^{-3}$ sec <sup>-1</sup>	$k_2/k_{un}$	$K_{diss}$ , $10^{-3} M$

<sup>a</sup> In pH 10.60 sodium carbonate buffer,  $I = 0.2$ , with 0.5% (v/v) added acetonitrile,  $25.0 \pm 0.1^\circ$ . <sup>b</sup> In pH 11.22 sodium phosphate,  $I = 0.2$ , with 0.5% (v/v) added acetonitrile,  $25.0 \pm 0.1^\circ$ .

Large hydrophobic substituents on guest molecules lead to the formation of relatively stable cycloamylose complexes. In an attempt to gain some understanding of the nature of the forces which lead to complex formation, the temperature dependencies of some cycloheptaamylose-substrate dissociation constants were examined using kinetic methods (Table VII). A

Table XI. Thermodynamic Changes for the Dissociation of Cycloheptaamylose Complexes<sup>a</sup>

10) This was qualitatively demonstrated by Hennrich and Cramer who showed that the presence of phenol in the reaction mixture reduced acceleration of the alkaline decomposition of diphenyl pyrophosphate.<sup>10</sup>

amylose is not very temperature dependent: the binding is due primarily to a favorable entropy change. However, the binding of *m*-ethylphenyl acetate is due to a favorable enthalpy change.<sup>41</sup> 3,4,5-Trimethylphenyl acetate exhibits intermediate behavior. Discussions and experimental data relating to hydrophobic binding indicate that a favorable entropy change is often involved.<sup>42-44</sup> One reason<sup>45</sup> for the sizable enthalpy change observed in the binding of *m*-ethylphenyl acetate is probably that water molecules in the cavity cannot form their full complement of hydrogen bonds as a result of steric restrictions. The data for *m*-chlorophenyl acetate is difficult to interpret on this basis but may be related to the fact that the aromatic chloro substituent is capable of forming hydrogen bonds<sup>46</sup> with water molecules which would be freed on complexation, leaving only a net entropy effect. The hypothesis that exclusion of water from the region of the cavity is an important factor in binding to the cycloamyloses is consistent with the fact that complexes may be readily formed with guest molecules which are too large to be completely included. Thus, for example, adamantanecarboxylate which cannot enter the cavity of cyclohexaamylose (Figure 9D) still forms a relatively stable complex,  $K_{dis}$  being  $7 \times 10^{-3} M$  (Table V). The inhibitor molecule is able to interact with a portion of the cyclohexaamylose cavity slightly past the region of the secondary hydroxyl groups. However, when the substrate is able to entirely exclude water from the region of the cavity, quite stable complexes may be formed. Cycloheptaamylose complexes of *m*-*t*-butylphenyl acetate and of adamantanecarboxylate, for example, have dissociation constants of  $1 \times 10^{-4} M$  and  $7 \times 10^{-4} M$ , respectively. Substrates which fill the cavity completely or have large hydrophobic areas which can interact with the ether-like interior of the cavity form the most stable cycloamylose complexes, so that it would appear reasonable to expect a relationship between the free energy of complex formation and the molecular volume of the guest. In fact, there is an approximate linear relationship between the logarithm of the dissociation constant and the value of the parachor of the guest, the parachor being taken as a measure of molecular volume.<sup>47</sup> Thus, for the cyclohexaamylose dissociation constants reported here (excluding only the carboxyphenyl esters) a correlation coefficient of 0.79 is found for the least-squares-fitted line. As might be expected for the series of structurally similar substrates and inhibitors considered here, nearly identical correlations were obtained with molecular weight and with molar refraction.<sup>48</sup>

(41) Similar observations have been made for the binding of aromatic amino acid derivatives to cycloheptaamylose: M. Laskowski, Jr., and T. L. Warrington, quoted in ref 8.

### Determination of Dissociation Constants by Inhibition Methods. In the reaction scheme

$K_i$  is the dissociation constant of the 1:1 cycloamylose-inhibitor complex  $\text{CA} \cdot \text{I}$ ,  $k_{\text{un}}$  is the spontaneous reaction rate constant of the substrate  $\text{S}$ ,  $K_{\text{diss}}$  is the dissociation constant of the 1:1 cycloamylose-substrate complex  $\text{CA} \cdot \text{S}$  (determined by independent kinetic methods as already described),  $k_2$  is the catalyzed reaction rate constant of the complexed substrate, and  $[\text{S}]_0$  and  $[\text{CA}]_0$  the initial stoichiometric concentrations of substrate and cycloamylose, respectively. The fraction  $F_c$  of complexed substrate will be<sup>22</sup>  $(k_{\text{obsd}} - k_{\text{un}})/(k_2 - k_{\text{un}})$ . Then

$$\begin{aligned}
 K_{\text{diss}} &= [\text{S}][\text{CA}]/[\text{CA} \cdot \text{S}] = [\text{S}_0 - \text{CA} \cdot \text{S}][\text{CA}]/[\text{CA} \cdot \text{S}] \\
 &= [(1 - F_c)/F_c][\text{CA}] \\
 &= [(1 - F_c)/F_c][\text{CA}_0 - \text{CA} \cdot \text{I} - \text{CA} \cdot \text{S}]
 \end{aligned}$$

but since  $[\text{A}_0 + \text{CA} \cdot \text{I}] \gg [\text{CA} \cdot \text{S}]$  this becomes

$$\begin{aligned}
 &= [(1 - F_c)/F_c](\text{CA}_0 - [\text{CA}][\text{I}]/K_i) \\
 &= [(1 - F_c)/F_c] \left( \text{CA}_0 - \frac{[\text{I}][\text{CA} \cdot \text{S}]K_{\text{diss}}}{[\text{S}]} \right) \\
 &= [(1/F_c) - 1] \left[ \frac{[\text{CA}_0 - [\text{I}]K_{\text{diss}}]}{K_i} \left( \frac{F_c}{1 - F_c} \right) \right] \\
 &= [(1/F_c) - 1]\text{CA}_0 - ([\text{I}]K_{\text{diss}}/K_i)
 \end{aligned}$$

so that on rearranging

$$\begin{aligned}
 [\text{I}] &= [(1/F_c) - 1][\text{CA}_0]K_i/K_{\text{diss}} - K_i \\
 &= \left( \frac{1/(k_{\text{obsd}} - k_{\text{un}})}{(k_2 - k_{\text{un}})} - 1 \right) \frac{[\text{CA}_0]K_i}{K_{\text{diss}}} - K_i \\
 &= \left( \frac{k_2 - k_{\text{obsd}}}{k_{\text{obsd}} - k_{\text{un}}} \right) \frac{[\text{CA}_0]K_i}{K_{\text{diss}}} - K_i
 \end{aligned}$$

Thus, by plotting the inhibitor concentration *vs.*  $(k_2 - k_{\text{obsd}})/(k_{\text{obsd}} - k_{\text{un}})$  an approximate straight line is obtained with intercept  $-K_i$  and slope  $([\text{CA}_0] \cdot K_i)/K_{\text{diss}}$ .

## The Mechanism of the Cycloamylose-Accelerated Cleavage of Phenyl Esters<sup>1-3</sup>

Robert L. VanEtten,<sup>4,5</sup> George A. Clowes, John F. Sebastian,<sup>4</sup> and Myron L. Bender

Contribution from the Department of Chemistry, Northwestern University, Evanston, Illinois 60201. Received January 6, 1967

**Abstract:** The release of phenols from a number of *meta*-substituted phenyl benzoates is accelerated in alkaline solution by cyclohexaamylose and cycloheptaamylose. The acyl portion is transferred to a hydroxyl group of the amylose, forming a cycloamylose benzoate which undergoes hydrolysis *via* a subsequent reaction at a rate independent of the nature of the phenolic group. Cyclohexaamylose benzoate was separated from phenol and unreacted *m*-nitrophenyl benzoate by gel filtration chromatography and was found to undergo hydrolysis at the same rate as the intermediate formed *in situ* during the acceleration of phenol release from a variety of *meta*-substituted phenyl benzoates (substituents on the phenyl group). The hydrolysis of cycloamylose benzoates (deacylation) conforms to a Hammett relationship with  $\rho = 1.6$ . The pH dependence of the initial rate acceleration (acylation) and of the deacylation reaction agrees with a dependence on a group of  $\text{p}K_a = 12.1$ . Heptamethylcycloheptaamylose (primary hydroxyl groups blocked) causes as large an acceleration of phenyl ester cleavage as native cycloheptaamylose, but dodecamethylcyclohexaamylose (primary hydroxyl and half of secondary hydroxyl groups blocked) causes a small inhibition of the hydrolysis. This is consistent with a proposed mechanism involving nucleophilic participation by an alkoxide ion derived from the secondary hydroxyl groups of the cycloamylose. The hydrolysis of cycloamylose benzoates occurs ~20 times more rapidly than would be predicted on the basis of simple steric and electronic considerations so that the deacylation step may be subject to general acid or general base catalysis by vicinal hydroxyl groups of the cycloamylose. The cycloamylose pathway of binding, acylation, and deacylation is formally similar to the pathway of chymotrypsin-catalyzed hydrolysis of esters. Comparisons of chymotrypsin catalyses and cycloamylose reactions are made, including a comparison of the second-order rate constants of these substances with substrates.

The cycloamyloses cause a markedly stereoselective acceleration of the release of phenols from substituted phenyl acetates, the rate accelerations with

*meta*-substituted esters being larger than with the corresponding *para*-substituted esters.<sup>3</sup> For example, 0.01 *M* cycloheptaamylose causes a 250-fold increase

in the rate of phenol release from *m*-*t*-butylphenyl acetate but only a 2.2-fold increase for the *para* analog. The rate effects are mediated by a cycloamylose-ester complex in solution, and the reaction system exhibits many characteristics of enzyme-catalyzed reactions.<sup>3</sup> Because the rate effects are independent of the stabilities of the respective complexes it appeared unlikely that the rate effects were due to an unusual medium effect such as has been observed<sup>6</sup> for the hydrolysis of alkyl hydrogen sulfate esters. Moreover, the stereospecificity of the rate accelerations can be readily interpreted only on the basis of an interaction of the secondary hydroxyl groups of the cycloamylose (derived from carbon atoms 2 and 3 of the individual glucose residues) with the carbonyl carbon of the ester. The carbonyl carbon of *para*-substituted phenyl esters can readily be placed in proximity to the primary hydroxyl groups (derived from carbon atom 6 of the glucose residues) of cyclooctaamylose whereas it cannot be placed in proximity to the secondary hydroxyl groups of cyclohexa- and -heptaamylose. Cyclooctaamylose causes a large acceleration of phenol release from both *m*- and *p*-*t*-butylphenyl acetate consistent with the fact that the cavity is so large that the carbonyl group of either ester may be placed in proximity to the secondary hydroxyl groups of the cycloamylose when the aromatic ring and the *t*-butyl group are included in the cavity.

The specific mechanism by which the cycloamylose hydroxyl groups accelerate the release of phenols from phenyl esters is not obvious since participation may occur by nucleophilic, general acid, or general base mechanisms.<sup>7</sup> Thus it is important to attempt to distinguish between these possible mechanisms. The isolation of cyclohexaamylose phosphate from heterogeneous alkaline reaction mixtures (where the cycloamyloses cause an acceleration of phenol release from diphenyl pyrophosphate) has been reported.<sup>8</sup> This observation suggested that the rate accelerations observed in the course of the present work might be the result of nucleophilic catalysis. The present investigation of the hydrolysis of substituted phenyl benzoates and of the pH dependence of the rate accelerations was therefore undertaken in order to determine the mechanisms by which the cycloamyloses exert their effects on phenyl ester hydrolysis reactions.

## Experimental Section

All melting points and boiling points are uncorrected. Aqueous solutions were made up with distilled or double-distilled water and reagent grade chemicals. Eastman Spectro grade acetonitrile was employed for stock solutions of esters and for reaction solvents. Elemental analyses were carried out by Micro-Tech Laboratories, Skokie, Ill. A Radiometer 4c pH meter was used for the determination of pH values.

Cyclohexaamylose and cycloheptaamylose were obtained and purified as already described.<sup>3</sup> Dodecamethylcyclohexaamylose was very kindly provided by Dr. Hermann Schlenk.<sup>9</sup> The preparation of hexamethylcyclohexaamylose and heptamethylcycloheptaamylose has been described.<sup>10</sup> The hexa(6-*O*-mesyl)cyclohexa-

amylose<sup>11</sup> was purified by recrystallization from methanol. The ultraviolet absorption spectrum of this compound revealed an absorption band ( $\lambda_{\max}$  259 m $\mu$ ) which was attributed to residual pyridine. Efforts to completely remove the impurity by dilute acid wash (pH 2.2) and vacuum drying were unsuccessful. The amount of pyridine was calculated to be less than 5% (by weight) based on the optical extinction coefficient of pyridine (ca. 3600 in water). The infrared spectrum (potassium bromide disk) indicated the presence of covalent sulfonate (bands at 1345 and 1180 cm<sup>-1</sup>) consistent with the literature value.<sup>12</sup>

*Anal.* Calcd for (C<sub>7</sub>H<sub>12</sub>O<sub>7</sub>S)<sub>6</sub>: C, 35.01; H, 5.04; S, 13.33. Found: C, 35.09; H, 4.95; S, 13.52.

Hepta(6-*O*-mesyl)cycloheptaamylose also showed a small absorption band attributed to residual pyridine (less than 2% by weight). The infrared spectrum showed bands at 1340 and 1165 cm<sup>-1</sup> which were attributed to covalent sulfonate.

*Anal.* Calcd for (C<sub>7</sub>H<sub>12</sub>O<sub>7</sub>S)<sub>7</sub>: C, 35.01; H, 5.04; S, 13.33. Found: C, 34.92; H, 5.19; S, 13.61, 14.02.

The mesyl compounds were relatively insoluble in water so that reactions in the presence of these compounds were carried out in 20.5% acetonitrile solution (v/v). The reported values of the pH are the observed values obtained for the aqueous acetonitrile solutions.

**Benzoate esters** were prepared by the Schotten-Baumann procedure using the appropriate benzoyl chloride (25 mmoles) and sodium phenolate (25 mmoles) in 40 ml of water. Solid esters were recrystallized from 95% ethanol and dried under vacuum.

*m*-*t*-Butylphenyl benzoate was obtained as a liquid; vacuum distillation through a 1 × 10 cm vacuum jacketed column gave the ester, bp 186–188° (11 mm).

*Anal.* Calcd for C<sub>17</sub>H<sub>18</sub>O<sub>2</sub>: C, 80.30; H, 7.12. Found: C, 80.12; H, 7.27.

*m*-Chlorophenyl benzoate after recrystallization was obtained as colorless crystals, mp 69–70° (lit.<sup>13</sup> mp 71–72°).

*m*-Nitrophenyl benzoate was obtained as colorless needles, mp 91–92° (lit.<sup>14</sup> mp 95°).

*m*-Chlorophenyl *p*-chlorobenzoate was obtained as colorless needles, mp 99–99.5° (lit.<sup>15</sup> 101.5°).

*Anal.* Calcd for C<sub>12</sub>H<sub>8</sub>Cl<sub>2</sub>O<sub>2</sub>: C, 58.42; H, 3.00; Cl, 26.59. Found: C, 58.52; H, 3.30; Cl, 26.06.

*m*-Chlorophenyl *m*-chlorobenzoate was obtained as colorless needles, mp 65–66°.

*Anal.* Calcd for C<sub>12</sub>H<sub>8</sub>Cl<sub>2</sub>O<sub>2</sub>: C, 58.42; H, 3.00; Cl, 26.59. Found: C, 58.67; H, 3.04; Cl, 26.40.

*m*-Chlorophenyl *p*-nitrobenzoate was obtained by reaction of *m*-chlorophenol (1.3 g, 10 mmoles) with *p*-nitrobenzoyl chloride (1.9 g, 10 mmoles) in dry pyridine (10 ml). The reaction mixture was heated to boiling for 5 min and then diluted with 200 ml of 5% hydrochloric acid. The resulting solid was separated, washed successively with several portions of dilute acid, dilute alkali, and water, and then dried under vacuum. The solid was then recrystallized twice from ethanol, being obtained as colorless needles, mp 96–97° (lit.<sup>16</sup> mp 101°).

*Anal.* Calcd for C<sub>17</sub>H<sub>9</sub>ClNO<sub>4</sub>: Cl, 12.79. Found: Cl, 13.03.

**Reaction Kinetics of Phenyl Benzoates.** The reactions of substituted phenyl benzoates in alkaline solution were studied spectrophotometrically using a Cary Model 14 recording spectrophotometer equipped with a thermostated cell holder and cell compartment, and 0–1.0 and 0–0.1 absorbance unit slide wires. The general experimental techniques have been described.<sup>3</sup> The final concentrations of benzoate esters were 1.6–2.0 × 10<sup>-5</sup> M while that of added acetonitrile was 0.5% (v/v) unless otherwise stated. The reactions of the phenyl benzoates shown in Table I occurred in two steps in the presence of 0.01 M cycloamyloses (see Results).

(11) The location of the mesyl groups on the primary hydroxyl groups of the cycloamylose (that is, the C-6 hydroxyl groups of the individual glucose residues) following this method<sup>10</sup> of preparation has been established by Drs. F. Parrish and L. Long, Jr. (private communication). For a contrasting example of the reactivity of mesyl chloride with both primary and secondary hydroxyl groups see R. C. Chalk, D. H. Ball, and L. Long, Jr., *J. Org. Chem.*, **31**, 1509 (1966).

l release of phenol (or phenoxide ion) followed by a slower appearance of benzoate ester. The appearance of phenol was followed to completion by observing the increase in absorbance at 390  $m\mu$ . After the absorbance reached a constant value the spectrophotometer was adjusted to permit the observation of benzoate ester disappearance at 245  $m\mu$  (or 260  $m\mu$  for *p*-nitrobenzoate disappearance). Because carbonate buffer absorbs very strongly at this wavelength, the slit width of the spectrophotometer was reduced. The infinite absorbance values were more sensitive to experimental errors and variations in instrumental operation than the small over-all absorbance change and slowness of the reaction. The estimated error for the phenol appearance reaction is  $\pm 3\%$ , while that for benzoate disappearance reactions is  $\pm 5\%$ .

The hydrolysis rate of *m*-*t*-butylphenyl benzoate in the absence of cyclohexaamylose was determined by extrapolation of data obtained in 10% (v/v) acetonitrile solution (apparent pH 12.75) on the basis of the known pH dependence of *m*-tolyl acetate hydrolysis and the hydrolysis rate in the acetonitrile solution. The estimated error of this rate constant is  $\pm 15\%$  while that of the spontaneous hydrolysis rate constants is  $\pm 5\%$ . A quantitative estimate of the amount of cycloamylose benzoate released during the course of the acylation of cycloamyloses by reaction with phenyl benzoates was made as follows. The observed change in absorbance during the alkaline hydrolysis of  $2.5 \times 10^{-4}$  *m*-methyl benzoate was 0.09 absorbance unit at 245  $m\mu$ . The cycloheptaamylose-accelerated hydrolysis of *m*-nitrobenzoate the average change in absorbance at 245  $m\mu$  (observed after completion of the initial phenol release reaction) was 0.084 absorbance unit, while in the presence of cyclohexaamylose the absorbance change in the second step of the reaction was 0.084 absorbance unit. Assuming that the extinction coefficients of the esters are not greatly perturbed in the presence of cycloamyloses (spectral perturbations of these compounds are relatively small) then the minimum amount of cycloheptaamylose benzoate released is  $\sim 70\%$ , while the minimum amount of cyclohexaamylose benzoate released is  $>90\%$ . Since the disappearance of benzoate was not followed until completion of the phenol appearance reaction it appears reasonable to conclude that the acylcycloamylose intermediate is produced in stoichiometric amounts during the course of the initial (phenol release) rate acceleration.

**Filtration Chromatography.** In order to effect a separation of cycloamylose benzoate and reaction products the following experiment was carried out. Cyclohexaamylose (0.10 g,  $1.0 \times 10^{-4}$  mole) was dissolved in 3 ml of pH 11 carbonate buffer. Fine particles of *m*-nitrophenyl benzoate (0.026 g,  $1.0 \times 10^{-4}$  mole) were added with 0.2 ml of acetonitrile. The reaction mixture was stirred vigorously for 5 min, brought to pH 3 with a few drops of hydrochloric acid, and filtered through a small glass wool plug to remove undissolved ester. The resulting solution was chromatographed using a  $1 \times 23$  cm column of Sephadex G-10 gel. The column was developed by eluting with distilled water. Consecutive 3-ml fractions were tested for the presence of cyclohexaamylose by consecutively spotting and drying four drops on filter paper and then spraying with 2% methanolic iodine solution. Cyclohexaamylose was found to be present in the first four fractions after passage of the void volume, consistent with the molecular exclusion limits of Sephadex G-10. Only traces of cyclohexaamylose were found in the subsequent fractions. After 15 fractions were collected, a 5-ml portion of pH 10.6 10% acetonitrile in carbonate buffer was passed through the column causing a distinct yellow band to appear *ca.* one-quarter of the way down the column. No *m*-nitrophenol or unreacted ester was present in the earlier fractions, as judged by spectral examination of neutral and the strongly basic solutions (made basic with sodium hydroxide).

Ultraviolet absorption spectra of fractions 2-4 showed maxima at 233, 274, and 280  $m\mu$  (shoulder) and were practically superimposable on the spectrum of ethyl benzoate or methyl benzoate.

ts

**Hydrolyses of Phenyl Benzoates.** The alkaline hydrolysis of substituted phenyl benzoates in buffered solutions follow first-order kinetics, the rate constants varying in the manner expected on the basis of electronic effects of the substituents. As anticipated from data obtained for phenyl acetates<sup>3</sup> the release

Figure 1. Hydrolysis of *m*-nitrophenyl benzoate at pH 10.6 in the presence of 0.01 *M* cyclohexaamylose; lower curve, change in optical density at 390  $m\mu$  due to *m*-nitrophenoxide ion appearance as a function of time (lower time scale); upper curve, subsequent reaction followed at 245  $m\mu$  (benzoate ester disappearance) as a function of time (upper time scale). For reaction conditions see Table I and the Experimental Section.

of the *meta*-substituted phenolic portion of the ester is considerably accelerated in the presence of 0.01 *M* cycloamyloses relative to the rate of alkaline hydrolysis at the same hydroxide ion concentration (Table I).

Table I. Rate Constants of the Cycloamylose-Catalyzed Reactions of Some Aryl Benzoates<sup>a</sup>

Ester	Alkaline hydrolysis	Rate constants, $10^{-4} \text{ sec}^{-1}$ 0.01 <i>M</i> cycloheptaamylose			
		290 or 390 $m\mu$	245 or 260 $m\mu$	290 or 390 $m\mu$	245 $m\mu$

<i>m</i> -Chlorophenyl <i>m</i> -chlorobenzoate		1140	16.6	107	6.5
<i>m</i> -Chlorophenyl <i>p</i> -nitrobenzoate	163	$>1500$	75 <sup>c</sup>		

<sup>a</sup> pH 10.6, 25°, 0.5% (v/v) acetonitrile-water solution,  $I = 0.2$ , carbonate buffer,  $[\text{ester}] \approx 1.6\text{--}2.0 \times 10^{-4} \text{ M}$ . <sup>b</sup> Obtained by extrapolation of data obtained for reaction in 10% (v/v) acetonitrile-water, pH 12.75, and comparison with similar data obtained for hydrolysis of *m*-tolyl acetate. <sup>c</sup> Determined at 260  $m\mu$ .

Most importantly, there is a significant change in the over-all reaction pathway in the presence of cycloamyloses. Figure 1 shows the time course of the reaction of  $2 \times 10^{-5} \text{ M}$  *m*-nitrophenyl benzoate in the presence of 0.01 *M* cyclohexaamylose at constant pH (10.6). The release of phenol (as measured by phenoxide ion appearance at 390  $m\mu$  where there is no significant absorption by the ester or by benzoate ion) occurs very rapidly, reaching completion in 30 sec (bottom curve, Figure 1). Upon completion of this reaction the spectrophotometer wavelength can be changed to 245  $m\mu$ , permitting the observation of a second rate process which occurs much more slowly (top curve, Figure 1) than does the liberation of the phenol.

Figure 2. Hammett plot for deacylation of cyclohexaamylose benzoates at pH 10.6. The log of the relative hydrolysis rate of cyclohexaamylose benzoates (Table I) is graphed as a function of the Hammett substituent constant  $\sigma^n$ .

The appearance of phenols during reactions of a number of *m*-phenyl-substituted benzoate esters occurs some 8–300 times more rapidly than does the subsequent rate process observed at 245  $m\mu$  (Table I). Significantly, although the rates of phenol release from *m*-*t*-butyl-, *m*-chloro-, and *m*-nitrophenyl benzoates in the presence of cyclohexaamylose differ by an order of magnitude, the rates of the subsequent reactions followed at 245  $m\mu$  are the same within experimental error. Similarly, although the rate of appearance of the phenol from *m*-nitrophenyl benzoate in the presence of cycloheptaamylose is more than an order of magnitude greater than that from *m*-chlorophenyl benzoate, the rates of the subsequent reactions are essentially the same. These results indicate that the same intermediate is formed during the course of the phenol release reaction and that this common intermediate then undergoes hydrolysis at a rate which is independent of the nature of the phenolic portion of the original ester. The observed identical rates of reaction for the subsequent rate process demand the interpretation that a common intermediate is formed whose decomposition is the rate-determining step. This interpretation together with the results of gel filtration chromatography (below) is consistent only with the interpretation that the intermediate is a cycloamylose benzoate.

In order to provide further support for this interpretation the effect of substitution of the benzoate portion of the ester was examined. The *m*-chlorophenyl esters of *p*-chloro-, *m*-chloro-, and *p*-nitrobenzoic acids were hydrolyzed in the presence of excess cycloamyloses. After completion of the rapid phenol release reaction the subsequent benzoate ester disappearance was followed at 245–260  $m\mu$ . The rate of the benzoate ester disappearance was increased by an amount consistent with the electronic effects of the substituent group on the benzoate ester (Table I, Figure 2). In fact the hydrolysis of cyclohexaamylose benzoates conforms to a Hammett relationship with  $\rho = 1.6$ , suggesting the absence of significant steric effects. The hydrolysis of cycloamylose benzoates was not dependent on cycloamylose concentrations up to  $10^{-2}$  *M*. Cyclohexaamylose ben-

Figure 3. Pseudo-first-order rate constant for release of the phenol from *m*-tolyl acetate as a function of pH; lower curve, spontaneous hydrolysis; upper curve, rate constant in the presence of  $5 \times 10^{-3}$  *M* cyclohexaamylose (data of Table II).

zoate undergoes hydrolysis somewhat more rapidly than does cycloheptaamylose benzoate; this may be a consequence of the greater steric hindrance by the amylose residue derived from seven glucose molecules.

In an attempt to obtain a sample of cyclohexaamylose benzoate from a solution similar to a reaction mixture, equivalent amounts of *m*-nitrophenyl benzoate and cyclohexaamylose were mixed together in an alkaline aqueous acetonitrile solution, resulting in a rapid appearance of *m*-nitrophenoxide ion. After a few minutes this mixture was neutralized and chromatographed on Sephadex G-10 (see Experimental Section), which resulted in the complete separation of both the phenol and the unreacted ester from the fractions containing the cyclohexaamylose. The ultraviolet absorption spectrum of the recovered cycloamylose fraction showed the presence of a material having a spectrum identical with that of alkyl benzoate esters such as ethyl benzoate. The cycloamylose benzoate had  $\lambda_{\max}$  233, 274, and 280  $m\mu$  (sh) in water. When the material was dissolved in pH 10.6 carbonate buffer it was found to undergo hydrolysis with a rate constant of  $4.6 \times 10^{-4}$   $\text{sec}^{-1}$ , identical with that of the cyclohexaamylose benzoate formed *in situ* (Table I). On the basis of the observed differences in optical extinction coefficients between alkyl benzoate esters and benzoate ion it was calculated that the yield (calculated on the basis of the ester used) of cycloamylose benzoate formed *in situ* approached 100% for reactions of esters such as *m*-nitrophenyl benzoate where there is a large differential between the rate of the phenol release reaction and the subsequent deacylation (see Experimental Section).

**pH Dependence of the Cycloamylose Rate Effects.** If the intermediate cycloamylose benzoates are produced by a nucleophilic displacement reaction by an alkoxide ion derived from the secondary hydroxyl groups of the cycloamylose it would be reasonable to expect a first-order dependence on hydroxide ion of the rate of phenol release ( $k_2$ ) and on the rate of the subsequent deacylation reaction ( $k_3$ ). To this end the pH dependence of both the acylation and deacylation reactions was examined (Table II). In Figure 3 is shown the pH dependence of the rate of phenol release from *m*-tolyl acetate in the presence of  $5 \times 10^{-3}$  *M* cyclohexaamylose

Figure 4. Maximal rates of acylation of cyclohexaamylose by *m*-acetate graphed as a function of pH (data of Table III).

curve) as well as the pH dependence of the hydrolysis reaction in the absence of cycloamylose (bottom e). The basic hydrolysis reaction of the ester obeys the expected first-order dependence on hydroxide ion, as does the accelerated reaction below pH 11. The acylation of cyclohexaamylose by *m*-tolyl acetate occurs some 22 times more rapidly than the line hydrolysis reaction in the pH range 9–11.

<sup>a</sup> Ionic strength = 0.2 throughout, with 0.5% (v/v) added acetonitrile,  $25 \pm 0.2^\circ$ . As many be seen from Figure 3, there appear to be specific effects observed when changing from one to the other buffer systems. <sup>b</sup> Cyclohexaamylose concentration  $5.0 \times 10^{-3} M$ . (The units of  $k$  are  $\text{sec}^{-1}$ .)

However, above pH 11 the rate acceleration begins to ease until at pH 13.1 there is observed only a sixfold acceleration. One interpretation of this result is that the cycloamylose molecule has become largely protonated so that further increases in hydroxide ion concentration will not result in a corresponding increase in cycloamylose alkoxide ion concentration; the hydroxide ion reaction will continue to increase in rate until after there are no longer any of the catalytically

Figure 5. Calculation of the kinetic  $pK_a$  value for acylation of cyclohexaamylose with *m*-tolyl acetate. The apparent ionization constant  $K_{app}$  for cyclohexaamylose is plotted vs. the fraction of cyclohexaamylose ionized (data estimated from Figure 4; see Appendix).

active hydroxyl groups left to ionize. An alternative interpretation is that the dissociation constant of the cyclohexaamylose-*m*-tolyl acetate complex is pH dependent. Thus, the observed rate effect might decrease because less of the ester is complexed at higher pH. To eliminate this possibility the maximal rates of acylation (phenol release,  $k_2$ ) were determined as a function of pH (Table III). These data for *m*-tolyl

11.63	$4.18 \pm 1.20 \times 10^{-1}$
12.40	$1.6 \pm 1.0$
12.80	$2.8 \pm 0.6$

<sup>a</sup> Ionic strength = 0.2 with 0.5% (v/v) added acetonitrile,  $25.0 \pm 0.1^\circ$ ; for buffers see Table II. <sup>b</sup> The maximal rate of acylation is determined by calculating the rate of phenol release in the presence of an infinite amount of cyclohexaamylose; for details see ref 3.

acetate are shown in Figure 4. Again the rate conforms to a first-order dependence on hydroxide ion below pH 11 but begins to fall off at higher pH. When the data of Figure 4 are transformed to a plot of  $K_{app}$  vs. fraction of hydrogen ions released (see Appendix), the  $pK$  of the catalytically active group is estimated to be  $11.8 \pm 0.4$  (Figure 5). When the rate of deacylation of cyclohexaamylose benzoate (prepared *in situ* by reaction with *m*-nitrophenyl benzoate) is determined as a function of pH (Table IV), a curve is obtained (Figure 6) which is similar to that obtained for the pH dependence of acylation. The pH dependence of deacylation also exhibits a first-order dependence of hydroxide ion below pH 11 but the rate increases less rapidly above this point. The data shown in this figure were used to calculate the  $pK$  of the ionizing group as shown in Figure 7 (see Appendix); this was found to be  $12.3 \pm 0.2$ . Thus, the rate effects caused by the cycloamyloses are dependent on an ionizable group with a  $pK = 12.1$  which

<sup>b</sup> Ionic strength = 0.2 with 0.5% (v/v) added acetonitrile, 25.0 ± 0.1°. <sup>c</sup> Data of Table I.

**Effects of Blocking Cycloamylose Hydroxyl Groups.** Since the hydroxyl groups of the cycloamyloses are almost certainly the catalytically active groups, the effect of substituting particular hydroxyl groups was examined in an attempt to identify which of the hydroxyl groups were required to produce large accelerations of the phenol release reaction. When both the 6 and 3 positions of the glucose residues of cyclohexaamylose are blocked by conversion to methoxyl groups<sup>9</sup> the resulting dodecamethylcyclohexaamylose is catalytically inactive. Indeed, the alkaline hydrolysis of *m*-nitro- and *m*-*t*-butylphenyl acetates is slightly inhibited (Table V) although these compounds show a large acceleration of the phenol release reaction with cyclohexaamylose. The observed rate reductions must

Figure 7. Calculation of the kinetic  $pK_a$  of cyclohexaamylose from data obtained for the hydrolysis of cyclohexaamylose benzoate. The apparent ionization constant  $K_{\text{app}}$  is plotted vs. the fraction of cyclohexaamylose ionized (data estimated from Figure 6; see Appendix).

be interpreted as the result of formation of a cycloamylose complex which protects the ester from reaction with hydroxide ion in solution.<sup>3</sup> It is not the result of a medium effect since methyl glucoside produces a small rate acceleration.<sup>3</sup>

<sup>a</sup> In pH 10.7 carbonate buffer with  $I = 0.2$ , 0.5% (v/v) added acetonitrile, 25°.

However, when only the primary (C-6) hydroxyl groups are blocked the rate accelerations observed for the cleavage of phenyl esters are at least as large as those produced by cyclohexa- and -heptaamylose. Hexamesylcyclohexaamylose and heptamesylcycloheptaamylose were prepared<sup>10,11</sup> and their effects on the rate of reaction of *m*-*t*-butylphenyl acetate were determined in aqueous acetonitrile solutions (see Experimental Section). Since the extent of complex formation was expected to be less in the presence of large amounts of acetonitrile<sup>3</sup> the dissociation constants of the cycloheptaamylose-*m*-*t*-butylphenyl acetate complex and the corresponding mesyl system were determined using methods previously described.<sup>3</sup> The values of  $k_2$  (the first-order rate constant of the fully complexed ester) as well as the values of  $K_{\text{dis}}$  (the dissociation constants of the complexes) are given in Table VI. As anticipated, the complex is less stable in the presence of large amounts of acetonitrile, the value of  $K_{\text{dis}}$  increasing from  $1 \times 10^{-4}$  M in 0.5% acetonitrile to  $2 \times 10^{-3}$  M in 20.5% solution. This is similar to results obtained for the effect of acetonitrile on the *m*-chlorophenyl acetate-cyclohexaamylose complex.<sup>3</sup> Most importantly the maximal rate effects  $k_2/k_{\text{un}}$  for the mesyl compound and for unchanged cycloheptaamylose are nearly the same. Thus, block-

the amylose hydroxyl groups at high pH.<sup>21</sup> These authors concluded that the pH dependence of the optical rotation changes was consistent with a pK of 12 or slightly higher. Such a value is in agreement with the results of the present study. More recently, studies on the thermodynamics of ionization of carbohydrate derivatives<sup>22</sup> showed that the pK of the (two adjacent) secondary hydroxyl groups of the ribose moiety of adenosine is 12.35. The relatively acidic hydroxyl groups of the cycloamylose are probably the result of a specific interaction involving the C-2 and C-3 secondary hydroxyl groups, just as in ribose. The existence of a hydrogen bond in the crystalline state between these hydroxyl groups has been noted.<sup>23</sup> The enhanced acidity of these hydroxyl groups may be due to the combined inductive effects of the relatively electronegative oxygen atoms and also to stabilization of the alkoxide ion by means of an intramolecular hydrogen bond to a neighboring hydroxyl group. Other workers are attempting to distinguish between these effects for ribose compounds.<sup>22</sup>

Since the facile methylation of ribose derivatives by diazomethane in the presence of base has been reported<sup>24</sup> it is tempting to speculate that such a reaction could be exhibited by the cycloamyloses. Noting that only one of the two types of secondary hydroxyl groups of cyclohexaamyloses is methylated in certain methylation reactions,<sup>9</sup> it is possible that this is the same group of pK = 12.1 determined in the present work. From the methylation data of Staerk and Schlenk,<sup>9</sup> leading to dodecamethylcyclohexaamylose, the reactive secondary hydroxyl groups would appear to be the C-3 hydroxyl groups (numbering the carbons of the individual glucose units). This conclusion is consistent with the fact that the dodecamethyl derivative causes no rate enhancement of the phenyl ester cleavage reaction. While it is difficult to assess steric hindrance accurately from an examination of molecular models, it appears that the presence of a methyl group on either the C-2 or C-3 hydroxyl group would not completely hinder the approach of the remaining hydroxyl (oxygen atom) to the carbonyl carbon of an included ester molecule. Thus, either the introduction of the first methyl group radically changes the reactivity of the other secondary hydroxyl groups or, more likely, the C-2 and C-3 hydroxyl groups differ significantly in their reactivity and acidity.

The deacylation step,  $k_2$ , in mechanism 1 depends on the electronic nature of the substituents on the benzoic acid portion of the ester but does not appear to be sensitive to differing steric patterns of *meta* and *para* substitution (Figure 2). The pseudo-first-order rate constant for the alkaline hydrolysis of cyclohexaamylose benzoate at pH 10.6 is  $4.6 \times 10^{-4} \text{ sec}^{-1}$  (Table I), corresponding to a second-order rate constant of  $1.2 \text{ M}^{-1} \text{ sec}^{-1}$ . The secondary ester isopropyl benzoate is a reasonable model for cyclohexaamylose benzoate with respect to linkage and steric hindrance; the second-order rate constant for the alkaline hydrolysis of iso-

propyl benzoate is  $0.6 \times 10^{-2} \text{ M}^{-1} \text{ sec}^{-1}$ .<sup>25</sup> Thus, cyclohexaamylose benzoate hydrolyzes 200 times more rapidly than does isopropyl benzoate. The difference in pK between cyclohexaamylose and isopropyl alcohol may account for a factor of 10 in rate<sup>26</sup> but it still appears that cyclohexaamylose benzoate hydrolyzes some 20 times more rapidly than would be expected on the basis of steric and electronic effects. This rate difference is presumably the result of general acid or general base catalysis of the deacylation step by adjacent hydroxyl group(s). Both types of catalysis would exhibit the leveling off in the rate of the deacylation reaction at high pH when the alkoxide ion is ionized (Figure 6). If, however, isopropyl benzoate is not a proper model for the steric hindrance to be expected in cyclohexaamylose benzoate, then it is possible that the latter ester does not hydrolyze unusually rapidly. In this event the leveling off in the rate of deacylation at high pH could be explained by electrostatic repulsion of partly ionized cycloamylose and hydroxide ion.

**Comparisons with Chymotrypsin.** The cycloamylose system may be compared with chymotrypsin catalysis in a number of respects. Chymotrypsin reactions are typically true catalyses. However, although cycloamylose reactions often show large increases in the rate of phenol release (the acylation reaction), there is true catalysis of over-all hydrolysis for only some of the esters studied. Of the esters listed in Table I, the over-all hydrolysis of *m-t*-butylphenyl benzoate is catalyzed by cyclohexaamylose, since the rate constant for alkaline hydrolysis of the ester at pH 10.6 is approximately four times less than the rate constant for hydrolysis of cyclohexaamylose benzoate. For the other esters of Table I, however, the deacylation rate constant is less than the rate constant for direct alkaline hydrolysis of the ester. The failure of the cycloamylose to catalyze the over-all hydrolysis of these esters is due to the relatively slow deacylation reaction, which is catalyzed by no more than 20-fold by adjacent hydroxyl groups, although the acylation reaction can be accelerated by many times that figure. In principle, there is no reason why more catalytically active general base or nucleophilic catalysts could not be introduced into the cycloamylose molecule, and thus make the analogy between cycloamylose and chymotrypsin more nearly complete.<sup>27</sup>

Both cycloamylose and chymotrypsin catalyze the hydrolysis of esters by the reaction scheme shown in eq 1. The reactant and catalyst form a complex in a rapid and reversible process described by a dissociation constant  $K_{\text{diss}} = k_{-1}/k_1$ . The similarity of the values of  $K_{\text{diss}}$  for chymotrypsin and for the cycloamyloses has been previously mentioned.<sup>3</sup> Both catalysts produce large rate effects in the acylation step. The magnitude of the rate effect depends on the stereochemistry of the substrate whereas the value of the dissociation constant of the respective complex is independent of the stereochemistry of the substrate.<sup>1</sup> However, the value of  $K_{\text{diss}}$  in the two systems does de-

(21) V. S. R. Rao and J. F. Foster, *Biopolymers*, **1**, 527 (1963); but see also V. S. R. Rao and J. F. Foster, *J. Phys. Chem.*, **69**, 636 (1965).

(27) The introduction of imidazole and amino groups onto the cycloamylose ring has recently been reported [F. Cramer and G. Mackensen, *Angew. Chem. Intern. Ed. Engl.*, **5**, 601 (1966)]. Rate effects of 3-4 were observed (relative to the effects produced by noncovalently bonded nitrogen bases and cycloamyloses) in the hydrolysis of *p*-nitrophenyl acetate at pH  $\sim 7$ .

d on the type of substituent groups in the substrate, the cycloamyloses and chymotrypsin preferentially ling apolar substrates. This is in contrast to the ation in, for example, trypsin, which preferentially ls cationic substrates.

oth chymotrypsin and the cycloamyloses have an hatic alcohol group at the active site which acts as acyl group acceptor during the catalysis of ester olysis.<sup>28</sup> Whereas the acylation step in reactions 1 the cycloamyloses depends on a hydroxyl group 1 a pK of 12, the acylation step in chymotrypsin- yzed reactions depends on a group with a pK of resumably the imidazole group of a histidine resi- .<sup>29</sup> The imidazole group is also active in the de- ation step. Mention has already been made of the arent 20-fold intramolecular catalysis of the deacyla- of cyclohexaamylose benzoate. Catalysis of the ylation step is thus a feature of both the cyclo- lose and chymotrypsin reaction systems but the h larger catalysis of chymotrypsin deacylations s to a large over-all catalysis of hydrolysis. In ad- on, the deacylation step in chymotrypsin-catalyzed tions is highly stereospecific, but this is not the case the deacylation of the cycloamyloses.

i the acylation reactions the reaction rates of notrypsin and of the cycloamyloses are very similar. i possible to calculate the second-order rate cons- ts for reaction of substrates with the cycloamyloses e following way. For the reaction scheme

assumption of a preequilibrium and the condition  $C_0 \gg E_0$  leads to the Michaelis-Menten equation  $1/t = k_2[C]_0/[E]_0/(K_{\text{diss}} + [C]_0)$ . If the condition posed that  $(C)_0 \ll K_{\text{diss}}$ , then a second-order rate ant can be determined from  $dP/dt = k_2[(C)_0 \cdot ]/K_{\text{diss}}$ . The values of the second-order rate con- ts calculated in this manner using the values of m) (the maximal rate constant of acylation of the r complexed ester in the pH region where the cyclo- lose is completely ionized<sup>30</sup>) and the dissociation ants of the respective complexes<sup>3</sup> are shown in le VII. Also shown in the table are corresponding es of  $k_{\text{cat}}(\text{lim})/K_m(\text{app}) (= k_2(\text{lim})/K_s)$ <sup>28</sup> for chymo- sin reactions.

he second-order rate constants of Table VII show he method of comparing cycloamylose or chymotryp- eactions with hydroxide ion reactions. The values able VII state the relative rates when equal amounts ycloamylose or hydroxide ion catalysts are used, or n equal amounts of chymotrypsin or hydroxide ion

**Table VII.** Second-Order Rate Constants for Reactions of Phenyl Esters with Cycloamyloses and of Substrates with Chymotrypsin

		$3 \times 10^4$

<sup>a</sup> Data for the cycloamylose reactions were obtained by division of the limiting value<sup>30</sup> of  $k_2$  (see text) by  $K_{\text{diss}}$  (ref 5). <sup>b</sup> M. L. Bender, G. E. Clement, F. J. Kézdy, and H. d'A. Heck, *J. Am. Chem. Soc.*, **86**, 3680 (1964). <sup>c</sup> M. L. Bender, F. J. Kézdy, and C. R. Gunter, *ibid.*, **86**, 3714 (1964). <sup>d</sup> D. J. Whelan and M. L. Bender, unpublished work. <sup>e</sup> H. Gutfreund, "An Introduction to the Study of Enzymes," John Wiley and Sons, Inc., New York, N. Y., 1965, p 296.

catalysts are used. On this basis, the cycloamylose reactions are clearly superior to the hydroxide ion reactions, as are the chymotrypsin reactions. In fact, the rate enhancements of the cycloamyloses with respect to hydroxide ion are approximately as great as the rate enhancements of chymotrypsin with respect to hydroxide ion. Does this mean that cycloamyloses are identical kinetically with chymotrypsin? The answer to this question is no, because  $k_2(\text{lim})$  is determined at *ca.* pH 13 for the cycloamylose while it is determined at *ca.* pH 8 for chymotrypsin. This comparison of Table VII is, however, a true indication of the effect of complexing on the rates of reaction. In that sense, cycloamyloses compare very well with chymotrypsin. If some method makes it possible to reduce the pH at which the cycloamylose acts without losing any of its other properties, it might be possible to come closer to chymotrypsin reactivity.

Cycloamylose-catalyzed and chymotrypsin-catalyzed hydrolyses of phenyl esters exhibit many similarities. Both catalyses occur by a similar pathway involving a rapid association to form complexes. The ester substrates then react with the catalyst to form an acylated intermediate, which subsequently undergoes hydrolysis in a slow step. The dissociation constants of binding of the two systems are similar, complex formation being best with apolar substrates. Increasing ionic strength of the solution tends to favor complex formation, while added apolar solvents decrease the stability of the complexes. Both systems are subject to competitive in-

) M. L. Bender and F. J. Kézdy, *J. Am. Chem. Soc.*, **86**, 3704 (1964), and references cited therein.

) For a recent study of the pH dependence of chymotrypsin-catalyzed reactions and references to previous work see M. L. Bender, M. J. Gunter, and D. J. Whelan, *Proc. Natl. Acad. Sci. U. S.*, **56**, 833 (1966).

) At pH 10.6, assuming that both cyclohexaamylose and cycloheptaamylose have a pK of 12.1, the ratio of ionized to un-ionized cycloamylose is  $3.1 \times 10^{-3}$ . The limiting rate of acylation of cyclohexaamylose by *m*-*t*-butylphenyl acetate assuming complete ionization will be  $(12.9 \times 10^{-3} \text{ sec}^{-1})/(3.1 \times 10^{-3})$  where  $12.9 \times 10^{-3} \text{ sec}^{-1}$  is the calculated rate of  $k_2$  at pH 10.6.<sup>3</sup> The limiting values of  $k_2$  calculated in this way for the acylation of cyclohexaamylose and cycloheptaamylose by *m*-*t*-butylphenyl acetate are 4.2 and 4.0  $\text{sec}^{-1}$ , respectively. No correction has been made for the fact that there are 6 or 7 equivalent hydroxyl groups in the cycloamylose; this correction would make the calculated values proportionately larger.

hibition by added organic molecules. The maximal rate effects produced in the two systems are unrelated to the *stabilities* of the complexes, but depend on their *stereochemistry*. The specific stereochemical relationships between the cycloamyloses and their substrates are well described on the basis of the three-dimensional structure of these materials. A similar description of enzyme-substrate interactions should be possible.

## Appendix

**Calculation of the Ionization Constant of Cyclohexaamylose from Kinetic Data.** For the compound  $AH_n$  capable of successive ionizations

Because the successive ionizations and reactivities of the cycloamylose alkoxide ions are probably perturbed by preceding ionizations it is desired to determine the value of  $K_1$ , the first ionization constant, as opposed to  $K_{app}$ , where

$$\begin{aligned} K_{app} &= \frac{[H^+][\text{no. of moles of charges on molecules}]}{[\text{no. of moles of undissociated molecules}]} = \\ &= \frac{[H^+](AH_{n-1}] + 2[AH_{n-2}] + \cdots + n[AH_{n-n}])}{[AH_n]} = \\ &= \frac{[H^+] \sum_{x=1}^n x[AH_{n-x}]}{[AH_n]} \end{aligned}$$

In the limit of single, kinetically productive ionizations then  $K_{app}$  will equal  $K_1$ .

Figures 3 and 4 show, in addition to a plot of values observed in the presence of cycloamylose  $k_c$ , a second

line based on extrapolation from the observed data at low pH and low fraction of ionization; the extrapolated rate constant at any pH may be designated  $k_{ex}$ . At any pH the fraction  $k_c/k_{ex}$  is equal to the fraction of undissociated amylose  $AH_n$ . That is

$$\begin{aligned} k_c/k_{ex} &= [AH_n] / \sum_{x=1}^n x[AH_{n-x}] \\ 1 - k_c/k_{ex} &= \frac{\sum_{x=1}^n x[AH_{n-x}]}{[AH_n]} \end{aligned}$$

Since also

$$K_{app} = [H^+] \sum_{x=1}^n x[AH_{n-x}] / [AH_n]$$

it is possible to calculate  $K_1$  by constructing a graph of  $K_{app}$  vs. fraction of ionized cycloamylose. Extrapolation to low fractions of ionization gives  $K_1$ . The appropriate values of  $1 - k_c/k_{ex}$  were taken from Figures 4 or 6, multiplied by the respective values of the pH to give  $K_{app}$ , and these values plotted in Figures 5 and 7, respectively. Extrapolation to low fractions of ionization gives the ionization constants. The kinetic  $pK_a$  value based on the acylation rate data is 11.8, while that for the deacylation rate data is 12.3. The uncertainty in these values is probably  $\pm 10\%$  for the deacylation rate data and  $\pm 30\%$  for the acylation rate data.

**Acknowledgment.** The authors thank Dr. Hermann Schlenk for kindly providing a sample of dodecamethylcyclohexaamylose and Dr. I. M. Klotz for helpful discussions regarding the calculation of ionization constants of polyprotic acids.

# Kinetic Studies on the Alkaline Decomposition of Cystine Derivatives and Peptides<sup>1</sup>

Oscar Gawron and Gerald Odstrchel<sup>2</sup>

Contribution from the Department of Chemistry, Duquesne University, Pittsburgh, Pennsylvania 15219. Received January 25, 1967

**Abstract:** Alkaline decomposition of endopeptides of cystine takes place *via*  $\beta$  elimination to give a persulfide moiety and a dehydroalanyl residue containing moiety. Rates of decomposition of N,N'-dicarbobenzyloxy-L-cystinyldiamide, N,N'-dicarbobenzyloxy-L-cystinyldiglycine, N,N'-dicarbobenzyloxy-L-cystinyldi-L-alanine, and oxidized glutathione are first order in substrate and hydroxyl ion concentrations with bimolecular rate constants at 90.5° of 2.0, 0.95, and 1.43 l. mole<sup>-1</sup> sec<sup>-1</sup>, respectively, for the first three compounds and 0.11 l. mole<sup>-1</sup> sec<sup>-1</sup> for oxidized glutathione at 80.5°. Rates of decomposition at 90.5° of L-cystine bishydantoin are first order in substrate and show a pH dependency, interpretable in terms of a single ionization with a  $pK_a$  of 7.56. Initial elimination from oxidized glutathione is followed by addition of the amino group of glutamic acid residues to the dehydroalanyl residue. This secondary reaction observed with oxidized glutathione does not occur in the presence of morpholine. Similarly, in the presence of morpholine, alkaline decomposition of ribonuclease yields only one lysinoalanine residue, four normally being observed.

Recent work of Bohak<sup>3</sup> on alkaline decomposition of cystinyl residues of proteins establishes  $\beta$  elimination as the route for such decompositions, the primary products being a dehydroalanyl residue<sup>4</sup> and a cysteinyl residue.<sup>5</sup> These decompositions of cystinyl peptides are similar, in principle, to the alkaline decomposition of L-cystine bisphenylhydantoin first reported by Bergmann and co-workers<sup>6</sup> and attributed to an elimination reaction. A similar elimination was noted by Andrews and Andrews<sup>7</sup> with L-cystine bishydantoin, pyruvic acid being found on treatment of the reaction mixture with acid. Tarbell and Harnish<sup>8</sup> proposed a  $\beta$ -elimination mechanism for such decompositions of disulfides, suggesting that removal of a proton from carbon  $\beta$  to sulfur gives a carbanion which undergoes elimination to yield olefin and persulfide anion.

To further explore this mode of alkaline decomposition of cystine endopeptides and analogous cystine derivatives, a kinetic study of the alkaline decomposition of N,N'-dicarbobenzyloxy-L-cystinyldiamide, the corresponding bisglycine and bis-L-alanine, and L-cystine bishydantoin was undertaken and the results are reported herein.

## Experimental Section

**Compounds.** N,N'-Dicarbobenzyloxy-L-cystine,<sup>9</sup> mp 123°, after recrystallizations from chloroform, was used for synthesis of the following compounds: N,N'-dicarbobenzyloxy-L-cystinyldiamide, mp 181–182°, after two recrystallizations from methanol, prepared according to Boehringer, *et al.*;<sup>10</sup> N,N'-dicarbo-

benzyloxy-L-cystinyldiglycine was prepared by the method of Du Vigneaud and Miller;<sup>11</sup> N,N'-dicarbobenzyloxy-L-cystinyldi-L-alanine, mp 158–159°, after recrystallization from dioxane, was prepared by adaptation of the Du Vigneaud and Miller<sup>11</sup> procedure for the preparation of the corresponding glycine peptide.

*Anal.* Calcd for C<sub>28</sub>H<sub>34</sub>N<sub>4</sub>O<sub>10</sub>S<sub>2</sub>: C, 51.70; H, 5.25; N, 9.85; S, 8.63. Found: C, 51.89; H, 5.38; N, 10.03; S, 8.34.

L-Cystine bishydantoin was synthesized from L-cysteine hydantoin by oxidation with iodine.<sup>12,13</sup>

**Kinetic Runs.** Substrate sufficient for 25.0 ml of approximately  $3.00 \times 10^{-3}$  M solution was placed in a 25.0-ml volumetric flask, and at zero time, 25.0 ml of buffer or sodium hydroxide solution at bath temperature was added. The flask was stoppered, inverted several times to dissolve the substrate, and returned to the constant temperature bath. Aliquots (1 ml) were removed at suitable intervals and analyzed for pyruvic acid by a modification of the enzymatic method.<sup>14</sup> The aliquots were quenched with 2.0 ml of 3 N hydrochloric acid and then refluxed for 2.5 hr to liberate, by hydrolysis,<sup>15</sup> pyruvic acid from the dehydroalanyl peptide formed by the decomposition. After cooling, the pH of the hydrolysis mixture was adjusted to 8.3–8.5 with 10 M sodium hydroxide and the volume was adjusted to 4.0 ml. An aliquot of this solution was then analyzed for pyruvic acid with reduced diphosphopyridine nucleotide and lactate dehydrogenase.

**Persulfide Analysis.** Kinetic runs were also monitored for alkyl persulfide, the analyses being carried out by modification of the procedure of Cavallini, *et al.*<sup>16</sup> A 0.1-ml aliquot of the reaction mixture was added to a mixture of 1.0 ml of 0.2 M borate buffer, pH 9.0, and 0.5 ml of 0.1 M sodium cyanide (adjusted to pH 9.0 with acid), and cyanolysis of the persulfide was permitted to proceed for 10 min at room temperature. Under these conditions (pH 9.0–9.5 of the cyanolysis reaction mixture), thiocyanate was not obtained from starting disulfide. At the conclusion of the cyanolysis period thiocyanate was estimated with ferric ion.

**Inorganic Sulfide, Sulfur, and Thiol Analyses.** Persulfide formed during the course of a kinetic run was not stable, and after its disappearance, decomposition products at the -2 and 0 oxidation level were analyzed for, as follows. Inorganic sulfide was determined by the method of Fogo and Popowsky<sup>17</sup> on a 0.2-ml aliquot of the reaction mixture for a kinetic run. Sulfur was

Figure 1. Typical first-order plots for the decomposition at 90.5° and several pH values, of DCCDA (N,N'-dicarbobenzyloxy-L-cystinyldiamide), DCCG (N,N'-dicarbobenzyloxy-L-cystinyldiglycine), and DCCA (N,N'-dicarbobenzyloxy-L-cystinyldi-L-alanine). Reactions followed by estimation of pyruvic acid after hydrolysis.

determined by the method of Meister, *et al.*,<sup>18</sup> the sulfur in a suitable aliquot being reduced to hydrogen sulfide with cysteine and the hydrogen sulfide formed being removed with nitrogen and trapped in alkaline zinc acetate solution. The sulfide ion was then estimated by the procedure given above. Inorganic sulfur was calculated as the difference between hydrogen sulfide before and after the reduction treatment. Thiol was determined by Ellman's method<sup>19</sup> on a 0.2-ml aliquot of the reaction mixture by addition of 3.0 ml of a 1 M phosphate buffer, sufficiently acid to give a final pH of 8, followed by 0.05 ml of the Ellman reagent [5,5'-dithiobis-(2'-nitrobenzoic acid)].

## Results and Discussion

The base-catalyzed  $\beta$  elimination observed with symmetrical disulfides derived from cystine may be written as

with the rate-controlling step either reaction 1 or reaction 2. With reaction 1 rate controlling, a first-order rate dependence on hydroxide ion concentration is expected and with reaction 2 rate controlling, a sigmoid curve is the expected relationship between rates and hydroxide ion concentrations. In both cases the reaction is expected to be first order in disulfide concentration.

The compounds studied showed the expected first-order dependency on disulfide concentration. With respect to hydroxide ion concentration, both possible dependencies were observed, rates of the three dicarbobenzyloxycystinylbisamides showing first-order dependency while rates of cystine bishydantoin decompositions showed a sigmoid curve relationship.

Figure 1 presents several typical first-order plots at a given pH (0.2 M borate buffers) for the decomposition at 90.5° of N,N'-dicarbobenzyloxy-L-cystinyldiamide (DCCDA), N,N'-dicarbobenzyloxy-L-cystinyldiglycine (DCCG), and N,N'-dicarbobenzyloxy-L-cystinyldi-L-

Figure 2. Plots of  $k'$ , apparent first-order rate constants, at 90.5° vs. hydroxide ion concentration for the several indicated compounds.

alanine (DCCA). Initial concentrations were  $3 \times 10^{-3}$  M and first-order kinetics were obeyed for some 70% of the reaction. The slope of each of the first-order plots yielded  $k'$ , the apparent first-order rate constants for the reaction, at a given pH where

$$v = k(\text{OH}^-)(\text{RSSR}) \quad (3)$$

and

$$k' = k(\text{OH}^-) \quad (4)$$

Plots of  $k'$  vs. hydroxide ion concentration (Figure 2) for the individual compounds gave straight lines passing through the origin, in agreement with eq 4, and  $k$ , the bimolecular rate constant, was calculated from the slopes of these lines. The values of  $k$  are 2.0, 0.95, and 1.43 l. mole<sup>-1</sup> sec<sup>-1</sup> for N,N'-dicarbobenzyloxy-L-cystinyldiamide, N,N'-dicarbobenzyloxy-L-cystinyldiglycine, and N,N'-dicarbobenzyloxy-L-cystinyldi-L-alanine, respectively.

As might be expected on the basis of structural similarities of the three N,N'-dicarbobenzyloxy-L-cystinylbisamides, and without regard to charge differences,  $k$  values are of the same order of magnitude. With regard to charge differences between the three compounds, it is apparent the negatively charged carboxylate groups are sufficiently removed from the reaction site so as not to interfere with approach of hydroxide ion. In this connection it may be noted that N,N'-dicarbobenzyloxy-L-cystine with its adjacent  $\alpha$ -carboxylate group is unreactive to hydroxide under the reaction conditions employed. It would seem that in this case electrostatic repulsion would be mainly responsible for lack of attack by hydroxide.

Although not encountered in the limited series investigated, it is possible that substitution of the glycine of carbobenzyloxycystinyglycine by other amino acids would lead to relatively larger rate effects. Such effects from amino acid residues with sufficiently large side chains could conceivably arise from steric hindrance and/or alteration in the solvent environment around the site of the reaction and, assuming a *trans* conformation as would be expected for the elimination, from hindrances to attainment of this conformation. These effects would be expected to be greater at lower temperatures. Preliminary investigation of temperature effects yielded bimolecular rate constants of  $2.83 \times 10^{-3}$  and  $0.31 \times 10^{-3}$  l. mole<sup>-1</sup> sec<sup>-1</sup> for N,N'-dicarbobenzyloxy-L-cystinyldiglycine and N,N'-dicarbobenzyloxy-L-cystinyldi-L-alanine, respectively, at 31° in sodium hydroxide solution. At this temperature  $k_{\text{glycine}}/k_{\text{alanine}}$

Figure 3. Plot of  $k'$  at  $90.5^\circ$  vs. pH for L-cystine bishydantoin. Reaction followed by estimation of pyruvic acid after hydrolysis.

is 9.1 while at  $90.5^\circ$  the corresponding ratio is 0.67 and it is clear that the rate effect of substitution of alanine for glycine is greater at the lower temperature.

Figure 3 presents a plot of  $k'$  vs. pH for the bishydantoin of L-cystine. The shape of the curve is that of an ionization curve with a  $pK$  in the vicinity of 7.5. A Henderson-Hasselbach plot of pH vs.  $\log k'/(k'_{\max} - k')$  gives a straight line with a slope of 0.82 rather than 1.00 as expected for a single ionization. However, inclusion of a correction term<sup>20</sup> for activity of the anionic species, the ionic strength of the buffer varying with the pH, gives the modified Henderson-Hasselbach equation, and a plot (Figure 4) of  $pH - \log \gamma_{A^-}$

$$pH - \log \gamma_{A^-} = pK + \log [k'/(k'_{\max} - k')] \quad (5)$$

vs.  $\log k'/(k'_{\max} - k')$  gives a straight line with a least-squares slope of 1.02 and intercept ( $pK_A$ ) of 7.56. Buffer effects were not noted, variation at pH 9.02 of total buffer concentration from 0.1 to 0.2 M not affecting rates. Accordingly the reaction rate may be viewed as dependent on a single ionization albeit secondary ionizations are possible and racemization may also be occurring.<sup>24</sup> A possible reaction mechanism is given in Figure 5, hydrogen attached to imide nitrogen being considered the most acidic. Tautomerization to a form such as that given in the figure would then provide an intermediate for the elimination. The  $pK_A$  value, 7.56 at  $90^\circ$  found for L-cystine bishydantoin, is considerably less than that, 9.12 at  $25^\circ$ , for hydantoin itself,<sup>26</sup> the imide group of the latter ionizing.<sup>27</sup> The lower value for the cystine hydantoin may be due in part to a temperature effect and in part to an acid-strengthening effect in the L-cystine hydantoin.

(20)  $-\log \gamma_{A^-}$  was evaluated as  $0.589/\mu$ ,<sup>21</sup> the numerical value at  $90^\circ$  being that given by Manov, *et al.*<sup>22</sup> The ionic strength at a given pH was calculated from the buffer anion concentration; total buffer concentration 0.2 M,  $pK_A = 8.88$  for the first ionization of boric acid. The  $K_A$  value was obtained by extrapolation to  $90^\circ$  of a  $\log K_A$  vs.  $1/T$  plot,  $K_A$  values at several temperatures being obtained from the literature.<sup>23</sup>

Figure 6 presents plots at several pH values of the time course of decomposition of dicarbobenzyloxy-L-cystinyldiglycine at  $100^\circ$ , the reactions being followed by pyruvic acid and alkyl persulfide analyses. Comparison of the kinetic curves for persulfide and pyruvic acid indicates a similar pH dependence for initial rates of appearance of the two products and alkyl persulfide instability under the reaction conditions. The mode of decomposition of the particular alkyl persulfides encountered is not known. Investigation of persulfide decomposition products after disappearance of persulfide from reaction mixtures gave results demonstrating the presence of alkyl mercaptan and sulfide ion but not sulfur. At  $100^\circ$ , pH 10.0 (0.2 M borate), the stoichiometric ratios of products per mole of dicarbobenzyloxy-L-cystinyldiglycine are 0.67 mercaptan, 0.67 sulfide ion, and 1.0 pyruvate, while at  $30^\circ$  in 0.1 M sodium hydroxide, the corresponding ratios are 0.73, 0.1, and 0.97. The data obtained at  $100^\circ$ , assuming completeness of transformations subsequent to persulfide de-

composition, suggest the decomposition stoichiometry shown in eq 6, where (X) would contain one R and two sulfur atoms with a net oxidation number of +2. On this basis the decomposition reaction might be written as

Since a search for a decomposition product containing sulfur at a higher oxidation level than zero was not attempted, further discussion is inappropriate albeit it may be stated that  $\text{RSSO}_2^-$  fits the requirements for such a product and a mechanism may be written similar to that proposed by Danehy<sup>28</sup> and by Danehy and Hunter<sup>29</sup> for the alkaline decomposition of certain symmetrical alkyl disulfides. On the above basis, the low yield of sulfide ion in 0.1 M sodium hydroxide at 30° may signify a different pathway or destruction of sulfide ion.

To further explore the scope of  $\beta$  elimination from cystine peptides, oxidized glutathione was investigated, the decompositions being carried out at 80.5° in 0.2 M phosphate buffers. Both products, the dehydroalanyl residue and alkyl persulfide, were unstable (Figure 7) and could not be used to follow the reaction. The reaction was followed by analysis for residual oxidized glutathione with reduced triphosphopyridine nucleotide in the presence of glutathione reductase.<sup>30</sup> Disappearance of oxidized glutathione followed first-order kinetics and a plot (Figure 8) of  $k'$ , the first-order rate constants for individual runs, vs. hydroxyl ion concentration gives a straight line passing through the origin. Decomposition of oxidized glutathione is, therefore, similar to the other cystine peptides, the reaction being bimolecular with a bimolecular rate constant at 80.5° of 0.11 l. mole<sup>-1</sup> sec<sup>-1</sup>. Disappearance of dehydroalanyl residue (pyruvic acid) was accompanied by loss of glutamic acid and appearance of a new amino acid as evidenced by amino acid analysis<sup>31</sup> following acid hydrolysis. While the structure of the new amino acid was not determined, its mode of formation is analogous to that of lysinoalanine and, presumably in this case, the amino group of the glutamic acid adds across the double bond of the dehydroalanine residue to give N-(DL-2-amino-2-carboxyethyl)-L-glutamic acid. Oxi-

dized glutathione in its behavior toward alkali is, thus, entirely similar to the several cystine-containing proteins that undergo alkaline decomposition<sup>3</sup> and can be used as a model for such protein studies.

In connection with alkaline decomposition of the four cystine residues of ribonuclease, it has been noted<sup>1</sup> that one of the four dehydroalanyl residues produced by the elimination reaction is rapidly converted by a consecutive reaction to a lysinoalanine residue while the other three are converted to lysinoalanine residues at a slower rate. In this laboratory we have noted<sup>11</sup> the appearance of only one lysinoalanine residue per mole of ribonuclease when the alkaline decomposition is allowed to proceed in the presence of 0.1 M morpholine, the other three being replaced by the corresponding morpholine adduct. This remaining lysinoalanine residue is most likely the one formed at the fastest rate and its formation indicates an intrachain proximity of the dehydroalanyl residue and  $\epsilon$ -amino group involved, such that competition from morpholine is precluded. On this basis location in the amino acid sequence of the particular lysine and particular cystine residue involved is of interest with regard to their spatial relation. While a lysine-adjacent cystine pair is a likely lysinoalanine precursor,<sup>3</sup> it is also possible that the single polypeptide chain is so looped as to bring together a lysine residue and a cystine residue that are removed one from the other in the sequence. Lysozyme with its four cystine residues, three of which, at least,

acid analyzer.

## Novel Analgesics and Molecular Rearrangements in the Morphine-Thebaine Group. I. Ketones Derived from 6,14-*endo*-Ethenotetrahydrothebaine<sup>1</sup>

K. W. Bentley and D. G. Hardy

*Contribution from the Research Laboratories, Reckitt and Sons Ltd., Kingston-upon-Hull, England. Received September 26, 1966*

**Abstract:** Several ketones II derived from 6,14-*endo*-ethenotetrahydrothebaine have been prepared by the Diels-Alder addition of certain  $\alpha,\beta$ -unsaturated ketones to thebaine, by the action of cadmium alkyls on the corresponding acid chloride II (R = Cl), and, in some cases, by the action of Grignard reagents on the corresponding ester II (R = OEt) which is the adduct of thebaine and ethyl acrylate. Both 7 $\alpha$  and 7 $\beta$  forms of the ketone II (R = Me), the ester II (R = OEt), and the nitrile III have been isolated. Attempts to convert the 7 $\alpha$  ketone II (R = Me) into the 7 $\beta$  isomer have resulted only in the formation of a ketol X (R = H). Many of the bases prepared in this work are potent analgesics. The reaction product obtained from thebaine methiodide and *p*-benzoquinone has been shown to be a charge-transfer complex and not a true Diels-Alder adduct.

For many years determined efforts have been made to produce an analgesic markedly superior to morphine by minor and major modifications of the molecule of the alkaloid. The major modifications have all been in the direction of making simpler structures, representing what are believed to be the features of the molecule responsible for its analgesic action.<sup>2</sup> Structural simplifications of this type, however, have not so far resulted in any marked separation of the desirable and undesirable effects. It has been postulated that the action of such compounds is due to the fit of their molecules onto receptor surfaces, which triggers off their physiological effects.<sup>3</sup> Compounds of structure more simple than that of morphine, however, being more flexible, would be expected to fit at least as easily as the alkaloid to each of the similar receptor surfaces associated with the different effects, thus reproducing all of the physiological effects of the alkaloid. These considerations led us to examine bases more complex and, in particular, more rigid than morphine in the hope that the reduced flexibility and the differences in peripheral shape between such compounds and other known analgesics would result in the new bases being unac-

ceptable at some of the receptor surfaces, and thus to a separation of the various effects.

Several series of such complex derivatives of codeine and thebaine, which are themselves derivatives of morphine, are accessible by the Diels-Alder addition of dienophiles to thebaine<sup>4</sup> and by chemical transformations of the resulting adducts,<sup>5</sup> and in these compounds the new two-carbon bridge across ring C renders the molecule rigid. Many of the compounds derived from thebaine in this way contain also a new reactive center, derived from the dienophile, at which further chemical reactions may be effected to yield bases of still greater peripheral complexity. Some of our early work along these lines has already been reported,<sup>6</sup> but the work was suspended owing to the difficulty experienced in securing adequate pharmacological appraisal of the compounds prepared. During the course of this work, however, it was found that the ketonic base I, obtained by the catalytic reduction of the adduct of thebaine and *p*-benzoquinone, is an analgesic with about one-seventh the potency of morphine, when tested in rats by the conventional techniques.

In further pursuit of this idea, the other known Diels-Alder adducts of thebaine, namely the aldehyde II (R = H), the ketones II (R = Me and Ph), the nitrile III, and the diester IV were prepared, together with a number of new analogous bases, and these were tested in animals for analgesic properties.

The addition of dienophiles to thebaine can occur readily only on the exposed face of the diene system, and gives rise to derivatives of 6,14-*endo*-ethenotetrahydrothebaine, the atom numbering of which is shown in formula II. The prefix *endo* implies disposition of the 6,14-etheno bridge "inside" the tetrahydrothebaine skeleton, that is, on the opposite side of the molecule to that occupied by the hydrogen atoms at positions 6 and 14 in tetrahydrothebaine itself. Addition of the dienophile to the exposed face of the diene system in two ways, leading to isomeric adducts differing in stereochemistry at C-7, can also be envisaged, and the isomers obtained in this way can be differentiated by the symbols  $\alpha$  and  $\beta$ , which have the same implications as when used in the steroid field. A careful examination of models of the  $7\alpha$  and  $7\beta$  forms of the ketone II ( $R = \text{Me}$ ), the aldehyde II ( $R = \text{H}$ ), the ester II ( $R = \text{OEt}$ ), and the nitrile III reveals that there is little difference in steric hindrance in the two forms, which might be expected, therefore, to be of comparable stability. The stereochemical factors generally governing the mode of addition in the Diels-Alder reaction would, however, be expected to give in this case mainly adducts having the  $7\alpha$  configuration, II and III. The addition of unsymmetrical dienophiles such as alkyl and aryl vinyl ketones, acrylic esters, and acrylonitrile to thebaine appears to take place under electronic control, giving rise exclusively to C-7-substituted tetrahydrothebaine derivatives, very careful examination of the products of addition of methyl vinyl ketone and ethyl acrylate to the alkaloid producing no evidence of the production of C-8-substituted compounds.

The primary adduct of thebaine and methyl vinyl ketone consists almost entirely of the  $7\alpha$  ketone II ( $R = \text{Me}$ ), mp  $122^\circ$ , but from the mother liquors of the crystallization of this base the  $7\beta$  ketone, mp  $200\text{--}201^\circ$ , has been isolated in 0.5% yield. That these two bases are indeed epimers at C-7, and not C-7 and C-8 ketones, was conclusively demonstrated by the base-catalyzed rearrangement of both isomers to the same product, which is the ketone VII ( $R = \text{Me}$ ). This base-catalyzed rearrangement, which will be discussed in detail in a later paper in this series,<sup>7</sup> is analogous to the con-

version of nepenthone (II,  $R = \text{Ph}$ ) into isonepenthone (VII,  $R = \text{Ph}$ ), and involves loss of the asymmetry at C-7 in the intermediate enolate ion V. A rational mechanism for this rearrangement,  $V \rightarrow VI \rightarrow VII$ ,<sup>8</sup> can only be devised if the  $\text{COCH}_3$  group is situated at C-7. The assignment of the  $7\alpha$  configuration to the base, mp  $122^\circ$ , and the  $7\beta$  configuration to the minor product, mp  $200\text{--}201^\circ$ , of the Diels-Alder reaction has been confirmed by detailed nmr spectroscopic studies.<sup>8</sup>

Attempts were made to convert the  $7\alpha$  ketone II ( $R = \text{Me}$ ) into an equilibrium mixture with the  $7\beta$  isomer by reversible enolization to the enolate ion V. The primary enolization of the ketone is, however, kinetically controlled, and leads to the enolate ion VIII, and this can react with unenolized ketone to give a ketol IX ( $R = \text{H}$ ) (see below). The ketolization is reversible, however, and under reversible enolizing conditions the thermodynamically more stable ion V will eventually be formed and reversible discharge of this ion should give an equilibrium mixture of  $7\alpha$  and  $7\beta$  ketones. In practice, however, the process is complicated by the ease with which the enolate ion V suffers rearrangement through the phenate ion VI to the ketone VII ( $R = \text{Me}$ ), which appears to be more stable than either of the C-7 epimers of the adduct II ( $R = \text{Me}$ ).

Although these equilibration experiments provide no evidence as to which of the two C-7 epimers of the ketone II ( $R = \text{Me}$ ) is the more stable, the formation of derivatives of the  $7\alpha$ -tertiary alcohol X ( $R = \text{R}'$ )

= Me) from bases in which the bicyclooctene system has been opened, described in part IV of this series,<sup>9</sup> suggests that in the alcohols the  $7\alpha$  form is the more stable.

Treatment of the adduct II ( $R = \text{Me}$ ) with 1 equiv of methylmagnesium iodide or other Grignard reagent gives little or no tertiary alcohol, the product being a viscous gum very similar in infrared absorption to the original ketone. The same product is obtained by the action of anhydrous magnesium iodide on the adduct, and it is shown by thin layer chromatography to consist of a mixture of the ketone II ( $R = \text{Me}$ ) (20%), a new base (75%), and the product VII ( $R = \text{Me}$ ) of base-catalyzed rearrangement (5%). This mixture on treatment with 0.1 equiv of potassamide in liquid ammonia rapidly affords a good yield of the ketone II ( $R = \text{Me}$ ), which is sparingly soluble in ammonia, and, when treated with an excess of methylmagnesium iodide, it gives an excellent yield of the tertiary carbinol X ( $R = R' = \text{Me}$ ), which is obtained directly from the ketone II ( $R = \text{Me}$ ) and an excess of this Grignard reagent (see following paper).

Separation of the main component of the mixture was achieved on alumina plates, and it was obtained as prisms, mp 151–152°, and found to be isomeric with the original ketone II ( $R = \text{Me}$ ). Its infrared spectrum shows carbonyl absorption at 1715  $\text{cm}^{-1}$ , and hydrogen-bonded hydroxyl absorption at 3490  $\text{cm}^{-1}$ . The intensities of these absorption bands relative to the adjacent C–H bands, at 1450 and 2950  $\text{cm}^{-1}$ , respectively, was 0.52 and 0.19, whereas the intensities of the carbonyl and hydroxyl absorption bands relative to the same C–H bands in the ketone II ( $R = \text{Me}$ ) and the tertiary alcohol X ( $R = \text{Me}$ ,  $R' = i\text{-Am}$ ) are 1.07 and 0.42, respectively. The new base must, therefore, be a double molecule containing one hydroxyl and one carbonyl group between two ethenotetrahydrothebaine units, and, since it is convertible back into the ketone II ( $R = \text{Me}$ ), can only be a ketol resulting from attack of the ketone by its own enolate ion. Enolization by Grignard reagents or anhydrous magnesium iodide would be irreversible and, hence, kinetically controlled and lead to the ion VIII, attack of which on the ketone would afford the ketol X ( $R = \text{H}$ ). That this does correctly represent the structure of the ketol was confirmed by dehydration of the ketol to an  $\alpha,\beta$ -unsaturated ketone by heating with 98–100% formic acid. Ketol formation from the ketone and the enolate ion V would lead to a product containing the part structure XI, dehydration of which to an  $\alpha,\beta$ -unsaturated ketone would be impossible.

The nmr spectrum of the ketol fully supports the assigned structure X ( $R = \text{H}$ ). The spectrum, ob-

tained on a 40-Mc/sec instrument, shows no signal attributable to  $\text{COCH}_3$ , but does show signals (in  $\delta$  units) at 6.58 (four aromatic H), a complex signal pattern from 6.2 to 5.4 attributed to two *cis*  $\text{CH}=\text{CH}$  systems in slightly different environments, and signals at 4.95 (OH), 4.61 ( $2\text{OCH}<$ ), 3.86 (two aromatic  $\text{OCH}_3$ ), 3.80 (three protons in the hydrogen-bonded C-6  $\text{OCH}_3$  group in the alcoholic part of molecule), 3.67 (three protons in the unbonded C-6  $\text{OCH}_3$  group in the ketonic part), 2.41 ( $2\text{NCH}_3$ ), and 1.17 ( $\text{CCH}_3$ ). It may be noted that the C-6 methoxyl group in the alcohol X ( $R = R' = \text{Me}$ ) gives a signal at  $\delta$  3.75 and that in the ketone II ( $R = \text{Me}$ ) gives a signal at  $\delta$  3.61.

Stereochemically, since enolization in this case does not involve C-7, both units in the ketol IX ( $R = \text{H}$ ) belong to the  $7\alpha$  series, and the formation of the  $7\alpha$  ketone in good yield on deketolization of the base with potassamide in liquid ammonia is in agreement with this representation.

The addition of ethyl acrylate to thebaine is also highly stereospecific, giving about 94% of the  $7\alpha$  ester II ( $R = \text{OEt}$ ) and 6% of the isomeric  $7\beta$  compound. That the major product has the same stereochemistry at C-7 as the adduct of thebaine and methyl vinyl ketone II ( $R = \text{Me}$ ) was demonstrated by the conversion of both adducts into the tertiary carbinol XI ( $R = R' = \text{Me}$ ) by methylmagnesium iodide. The nmr spectra of the esters show signals (in  $\delta$  units) for the C-5 proton at 4.60 ( $7\alpha$ ) and 5.17 ( $7\beta$ ) compared with 4.55 and 4.98 in the spectra of the  $7\alpha$ - and  $7\beta$ -methyl ketones. The other features of the spectra are entirely in accord with the assigned structures.

The primary adduct of thebaine and acrylonitrile is a mixture of  $7\alpha$  and  $7\beta$  isomers from which, after treatment with charcoal, approximately equal amounts of the two pure isomers can be obtained by chromatography. The  $7\alpha$  nitrile III is identical with the product of dehydration of the oxime of the aldehyde II ( $R = \text{H}$ ) previously reported.<sup>5d</sup> The assignment of configuration at C-7 in these nitriles was made on the basis of detailed nmr studies.<sup>8</sup>

Although aryl vinyl ketones are readily prepared in the laboratory from aryl methyl ketones, alkyl vinyl ketones, other than the methyl and ethyl compounds which are commercially available, are not readily accessible, and attempts were made to prepare 7-acyl-6,14-endo-ethenotetrahydrothebaines from the ester II ( $R = \text{OEt}$ ) and the nitrile III. Some ketones were obtained in poor yield as minor products from the reaction of the ester II ( $R = \text{OEt}$ ) with Grignard reagents. With methylmagnesium iodide the sole product of this reaction is the tertiary carbinol XI ( $R = R' = \text{Me}$ ), but with other alkylmagnesium halides the product consisted of a mixture of tertiary carbinol X ( $R = R' = \text{Me}$ ), ketone II, and phenolic material resulting from rearrangement of the ester.<sup>9</sup> The amount of tertiary carbinol produced decreased and the amount of phenolic material obtained increased very rapidly as the length and/or branching of the alkyl chain in the Grignard reagent increased; the amount of ketone produced remained low in all cases. Steric factors are presumably operative in this reaction, since the ease of accommodation of two identical alkyl groups around the carbon atom of the tertiary alcohol, in the presence of the large thebaine unit, would be

(9) K. W. Bentley, D. G. Hardy, and B. Meek, *J. Am. Chem. Soc.*, **89**, 3293 (1967).

expected to decrease sharply as the complexity of the alkyl group increases. The ease of abstraction of a proton by the Grignard reagent from the  $\alpha$  carbon would be expected to be almost independent of the size of the reagent, and hence rearrangement would be expected to be favored relative to carbinol formation by an increase in size or complexity of the reagent.

A better laboratory preparation of certain of the ketones of structure II was found to be the reaction between cadmium alkyls and the acid chloride II ( $R = Cl$ ), prepared from the ester II ( $R = OEt$ ) *via* the acid II ( $R = OH$ ). The product of the reaction between the acid chloride and *n*-propylcadmium was resolved on alumina plates into the  $7\alpha$ -*n*-propyl ketone II ( $R = n\text{-Pr}$ ) (80%), its  $7\beta$  epimer (0.1%), the ketol X ( $R = Et$ ) (20%), and a trace of phenolic base. The major product was identified as the  $7\alpha$ -*n*-propyl ketone II ( $R = n\text{-Pr}$ ) by its infrared and its nmr spectra. The former showed carbonyl absorption at  $1715\text{ cm}^{-1}$  and the latter showed a signal due to the C-5 proton as a finely split doublet at  $\delta$  4.55 (as in the spectrum of the  $7\alpha$ -methyl ketone) as well as signals (in  $\delta$  units) at 6.6 (two aromatic H), 6.0 and 5.55 (doublets,  $\text{CH}=\text{CH}$ ), 3.83 (C-3  $\text{OCH}_3$ ), 3.61 (C-6  $\text{OCH}_3$ ), 2.29 ( $\text{NCH}_3$ ), and 0.95 (doublet,  $\text{CHC}_3$ ). The  $7\beta$  ketone was identified by its infrared spectrum, which was almost identical with that of the  $7\alpha$  isomer, and by its less polar behavior on thin layer chromatography.

The ketol IX ( $R = Et$ ) showed carbonyl and hydrogen-bonded hydroxyl absorption in the infrared, and its nmr spectrum was similar to that of the ketol IX ( $R = H$ ), showing signals (in  $\delta$  units) at 6.59 (four aromatic H), 5.45–6.1 (complex, 2  $\text{CH}=\text{CH}$ ), 4.6 and 4.75 (two C-5 H), 3.82 (9 H, two C-3  $\text{OMe}$ , C-3'  $\text{OMe}$ , and C-6'  $\text{OMe}$ ), 3.64 (3 H, C-6  $\text{OMe}$ ), 2.31 and 2.36 (2  $\text{NMe}$ ), and complex signals due to  $\text{CCH}_3$  in the region 1.38–0.98 attributed to the ethyl and propyl groups.

The ethyl and *n*-propyl ketones prepared in this way were converted by the action of methylmagnesium iodide into tertiary alcohols X ( $R = Et$ ,  $R' = \text{Me}$  and  $R = n\text{-Pr}$ ,  $R' = \text{Me}$ ) diastereoisomeric at C-19 with those ( $R = \text{Me}$ ,  $R' = Et$  and  $R = \text{Me}$ ,  $R' = n\text{-Pr}$ ) obtained by the reaction of the  $7\alpha$  ketone II ( $R = \text{Me}$ ) with ethyl- and *n*-propylmagnesium halides, respectively (see following paper).

The adduct of thebaine and acrylonitrile (mixture of  $7\alpha$  and  $7\beta$  isomers) reacts readily with methyl and other alkylmagnesium halides, but the reaction involves only base-catalyzed rearrangement, the same product being obtained in all cases. This reaction is discussed in detail in a later paper in this series.<sup>9</sup> With phenylmagnesium bromide, however, the  $7\alpha$  ketone, nepenthone (II,  $R = \text{Ph}$ ), was obtained in about 25% yield (about 50% based on the amount of  $7\alpha$ -nitrile present in the original adduct), and the *o*- and *p*-tolyl analogs were prepared in a similar manner. Differences in the behavior of nitriles with aliphatic and aromatic Grignard reagents have previously been reported.<sup>10</sup>

It was hoped that ketones II would be preparable by the oxidation of the related secondary alcohols X ( $R = H$ ), many of which can be prepared by the action of Grignard reagents on the aldehyde II ( $R = H$ ), but neither of the diastereoisomeric alcohols X ( $R$

$= H$ ,  $R' = \text{Me}$  and  $R = \text{Me}$ ,  $R' = H$ ) (see following paper) nor nepenthol (X,  $R = \text{Ph}$ ,  $R' = H$ )<sup>5b</sup> could be oxidized in this way.

Quaternization of the Diels–Alder adducts of thebaine is very difficult to accomplish, but good yields of the quaternary salts of the ketone II ( $R = \text{Me}$ ) and the ester II ( $R = \text{OEt}$ ) were obtained by heating the bases under reflux for 7 days with methyl iodide in acetone solution. Since the adducts of thebaine with acetylenic dienophiles can be quaternized with much greater ease, the sluggish reaction of the adducts II may be attributed to steric hindrance of attack of the nitrogen atom by the proximity of the C-8 $\beta$  hydrogen. It may be mentioned that other workers have found that this proximity and anisotropy of the tertiary nitrogen also appear to affect the resonance of the  $8\beta$  hydrogen in the nmr spectra of bases in this series.<sup>8</sup> Models of the quaternary salts can be constructed without difficulty, and in these there is no appreciable hindrance between this hydrogen atom and the N-methyl group. The slow quaternization of the adduct II ( $R = \text{Me}$ ) contrasts markedly with the rapid reaction between thebaine methiodide and benzoquinone<sup>11</sup> and  $\alpha$ -naphthaquinone<sup>4</sup> previously reported. Since attempts to prepare quaternary salts of the adducts by the addition of acrolein, methyl vinyl ketone, phenyl vinyl ketone, ethyl acrylate, acrylonitrile, and maleic anhydride to thebaine methiodide were quite unsuccessful, the reaction between methiodide and *p*-benzoquinone has been reexamined.

The reaction in chloroform solution rapidly affords a very good yield of a red crystalline solid having the composition of a 1:1 adduct, which is recovered unchanged on rapid recrystallization from hot water.<sup>11</sup> The use of high-boiling solvents, such as cyclohexanol, for the recrystallization, however, results in the recovery of thebaine methiodide, which is also obtained when the solid is heated in open vessels at 140–150°. Reduction of a solution of the salt in aqueous ethanol with sodium borohydride or sulfurous acid proceeds with the production of a transient violet color, presumably due to quinhydrone, and the formation of hydroquinone and thebaine methiodide. The material is, therefore, clearly not a true adduct, but is a charge-transfer complex of thebaine methiodide with benzoquinone, representing the initial stage in the Diels–Alder reaction. The reaction is prevented from proceeding to completion by steric hindrance to a sufficiently close approach of the two molecules for bond formation, as a result of the presence of the additional methyl group on the nitrogen atom. The examination of models shows that such steric hindrance would be expected to be operative in preventing the addition of other dienophiles to thebaine methiodide, and in these cases the charge-transfer complexes are presumably insufficiently well stabilized for them to be isolated.

Neither methyl isopropenyl ketone nor crotonaldehyde gives adducts with thebaine at temperatures up to 140°, but the examination of models of the expected adducts shows that steric hindrance in the molecules is no greater than in the ketone II ( $R = \text{Me}$ ), its  $7\beta$  isomer, or its methiodide. The failure of the reaction in these cases must be attributed to steric hindrance to a sufficiently close approach of the reactants for the forma-

(10) M. S. Kharasch and O. Reinmuth, "Grignard Reactions of Non-Metallic Substances," Constable and Co. Ltd., London, 1954, p 773.

(11) K. W. Bentley, R. Robinson, and A. E. Wain, *J. Chem. Soc.*, 938 (1952).

tion of the new bonds to C-6 and C-14, and the study of models of the reactants supports this view. With crotonaldehyde, which has the  $\text{CH}_3$  and  $\text{CHO}$  groups in the *trans* relationship, close approach to thebaine in such a way as to ensure maximum overlap of the unsaturated centers is severely hindered by carbon atoms 15 and 16 of the nitrogen-containing ring of the alkaloid. With methyl isopropenyl ketone, the hindrance is largely between the methyl group and the hydrogen atoms at C-5 and C-15 in the base. Maleic anhydride and *p*-benzoquinone, which have *cis*-1,2-disubstituted double bonds, can easily be brought into close proximity to the diene system of thebaine and form adducts with great ease.

Of the ketones of general structure II prepared in this work and listed in the Experimental Section, several were found to be more potent as analgesics than morphine, when tested in rats by the tail pressure method and administration by the subcutaneous route. By contrast, the ester II ( $\text{R} = \text{OEt}$ ) showed no analgesic activity at doses up to 200 mg/kg.<sup>12</sup>

## Experimental Section

**Addition of Methyl Vinyl Ketone to Thebaine.** Thebaine (1000 g) was boiled under reflux with methyl vinyl ketone (3 l.) for 1 hr. The excess of unsaturated ketone was removed by distillation under reduced pressure, and the viscous residue was dissolved in boiling methanol (1200 ml). The resulting solution was cooled in ice with vigorous stirring. The crystalline solid that separated was collected, washed with ice-cold methanol, and air dried, when 7 $\alpha$ -acetyl-6,14-*endo*-ethenotetrahydrothebaine (II,  $\text{R} = \text{Me}$ ) (1140 g, 93%) was obtained as white prisms, mp 119–121°, sufficiently pure for all chemical purposes, the melting point raised to 122° (lit.<sup>14</sup> 122°) on recrystallization from methanol,  $\nu_{\text{max}}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4$ : C, 72.4; H, 7.1. Found: C, 72.3; H, 7.1.

The hydrochloride formed white prisms, mp 262°, from ethanol.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4 \cdot \text{HCl}$ : C, 66.1; H, 6.7. Found: C, 66.4; H, 6.8.

The hydrobromide formed white prisms, mp 270°, from 90% ethanol.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4 \cdot \text{HBr}$ : C, 59.7; H, 6.1. Found: C, 59.9; H, 6.1.

The methiodide formed slowly when the base was heated under reflux with methyl iodide in acetone for 7 days. On recrystallization from aqueous ethanol it was obtained as prisms, mp 172°.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4 \cdot \text{CH}_3\text{I} \cdot \text{H}_2\text{O}$ : C, 53.3; H, 6.0. Found: C, 53.4; H, 6.2.

The mother liquors from the separation of the 7 $\beta$ -acetyl compound were concentrated to 400 ml and kept at room temperature overnight, when crystalline material separated. This was collected, washed with ice-cold methanol, and dried (14 g). Thin layer chromatographic studies showed this base to comprise a mixture of about 40% of the 7 $\alpha$  ketone II ( $\text{R} = \text{Me}$ ) and 60% of a less polar base. The solid was boiled under reflux with methanol (50 ml) when the more soluble 7 $\alpha$  ketone dissolved. The insoluble 7 $\beta$ -acetyl-6,13-*endo*-ethenotetrahydrothebaine (6 g) was collected and recrystallized from ethanol, when it was obtained as white rectangular plates, mp 200–202°, subliming slowly above 180°,  $\nu_{\text{max}}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4$ : C, 72.4; H, 7.1. Found: C, 72.4; H, 7.0.

The hydrochloride was obtained as white prisms, mp 266°, from ethanol-ether.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4 \cdot \text{HCl}$ : C, 66.1; H, 6.7. Found: C, 66.3; H, 6.8.

The hydrobromide was obtained as white prisms, mp 254°, from ethanol.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_4 \cdot \text{HBr}$ : C, 59.7; H, 6.1. Found: C, 60.0; H, 6.3.

Concentration of the mother liquors from the separation of this base and from the isolation of the 7 $\alpha$ -7 $\beta$  mixture gave a further

30 g of a mixture estimated by thin layer chromatography to contain about 70% of the 7 $\alpha$  ketone and 30% of the 7 $\beta$  isomer, and this material was recovered unchanged in composition after boiling with, or recrystallization from, methanol. Allowing for material present in this mixture the Diels-Alder reaction affords a yield of at least 97.8% of adduct: 96.3% 7 $\alpha$  and 1.5% 7 $\beta$  ketone.

**Addition of Acrolein to Thebaine.** On several occasions excellent yields (>85%) of the adduct were obtained by heating thebaine (25 g) with acrolein (75 ml) under reflux for 1 hr, removing the excess of acrolein by evaporation under reduced pressure, and crystallizing the residue from aqueous methanol. This process is, however, capricious and other reactions carried out under apparently identical conditions yielded only insoluble polymerized material from which neither adduct nor thebaine could be recovered. Neither careful purification of the reactants nor the addition of hydroquinone appeared to have any effect on the ease of polymerization. A more reliable process giving, however, a reduced yield of product was the following. A mixture of thebaine (25 g), benzene (250 ml), and acrolein (10 ml) was heated at 65–70° for 4 hr. The basic material was extracted from the benzene solution with aqueous 2 *N* acetic acid and then precipitated with ammonia. The crystalline material was collected, washed well with water, and recrystallized from aqueous methanol, when 6,14-*endo*-etheno-7 $\alpha$ -formyltetrahydrothebaine (II,  $\text{R} = \text{H}$ ) (17 g) was obtained as white prisms, 106° (lit.<sup>14</sup> 104°),  $\nu_{\text{max}}$  1730  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{22}\text{H}_{25}\text{NO}_4$ : C, 72.0; H, 6.8. Found: C, 72.2; H, 6.9.

**6,14-*endo*-Etheno-7 $\alpha$ -propionyltetrahydrothebaine (II,  $\text{R} = \text{Et}$ ).** Thebaine (25 g) was heated with ethyl vinyl ketone (25 g) in the presence of a small amount of hydroquinone at ~100° for 4 hr. The excess of ethyl vinyl ketone was removed under reduced pressure, and the dark viscous residue was dissolved in warm glacial acetic acid (25 ml). This solution was diluted with water (300 ml) and extracted with ether. The aqueous phase was freed from ether by boiling and basified (100 ml, 20% w/v aqueous sodium hydroxide), and the precipitate was collected, washed with water, and dried to give the adduct, mp ~40° (80%).

The base was converted into its hydrochloride with ethereal hydrogen chloride; the salt was recrystallized from ethanol (twice) and then converted into the base, mp 40–45°, with aqueous sodium hydroxide.

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4$ : C, 72.9; H, 7.4; N, 3.5. Found: C, 73.6; H, 7.6; N, 3.6.

**Addition of Ethyl Acrylate to Thebaine.** Thebaine (500 g) was boiled under reflux with ethyl acrylate (850 ml) for 6 hr. The excess of ethyl acrylate was removed by evaporation under reduced pressure until separation of the solid matter began. The mixture was centrifuged, the solid obtained was washed well with cold methanol, when 6,14-*endo*-etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (500 g) was obtained as white prisms, mp 123–124°, raised to 124° by recrystallization from methanol,  $\nu_{\text{max}}$  1740  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4$ : C, 70.0; H, 7.1. Found: C, 70.0; H, 7.3.

The hydrochloride, prepared in and recrystallized from ethanol, was obtained as white prisms, mp 258°.

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4 \cdot \text{HCl}$ : C, 64.4; H, 6.7. Found: C, 64.3; H, 6.7.

The methiodide formed slowly when the base was boiled under reflux in acetone with an excess of methyl iodide for 7 days and was obtained as white prisms, mp 240°, from ethanol.

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4 \cdot \text{CH}_3\text{I}$ : C, 54.3; H, 5.8. Found: C, 54.3; H, 5.8.

The mother liquors and methanol washings remaining after removal of the 7 $\alpha$  ester were evaporated under reduced pressure and the residual gum was dissolved in methanol (150 ml) and cooled in ice. The solid matter (60 g), consisting of an approximately 1:2:1 mixture of the 7 $\alpha$  and 7 $\beta$  esters and thebaine, was crystallized twice from methanol, when 6,14-*endo*-etheno-7 $\beta$ -ethoxycarbonyltetrahydrothebaine (9 g) was obtained as white prisms, mp 106–108°,  $\nu_{\text{max}}$  1740  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4$ : C, 70.0; H, 7.1. Found: C, 69.6; H, 7.0.

The hydrochloride formed white prisms, mp 198–200°.

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_4 \cdot \text{HCl}$ : Cl, 7.9. Found: Cl, 7.8.

**6,14-*endo*-Ethenotetrahydrothebaine-7 $\alpha$ -carboxylic Acid (II,  $\text{R} = \text{OH}$ ).** 6,14-*endo*-Etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (50 g) was heated on the water bath with concentrated hydrochloric acid (250 ml) for 3 hr. The filtered hot solution was cooled in ice and the crystalline solid that separated was collected and washed

(12) R. E. Lister, *J. Pharm. Pharmacol.*, 16, 364 (1964).

with ice-water, when the hydrochloride of the 7 $\alpha$ -carboxylic acid (47 g) was obtained as white prisms, mp 246–247°.

*Anal.* Calcd for  $C_{22}H_{31}NO_5 \cdot HCl \cdot H_2O$ : C, 61.6; H, 6.3. Found: C, 61.2; H, 6.7.

The free acid was obtained by continuous ether extraction of an aqueous solution of the hydrochloride adjusted to pH 6.1. Evaporation of the ether extract afforded a solid which was recovered on recrystallization from ethanol as white prisms, mp 230°.

*Anal.* Calcd for  $C_{22}H_{31}NO_5 \cdot 1.5H_2O$ : C, 64.4; H, 6.9. Found: C, 64.6; H, 6.9.

**7 $\alpha$ -Chlorocarbonyl-6,14-endo-ethenotetrahydrothebaine Hydrochloride.** 6,14-endo-Ethenotetrahydrothebaine-7-carboxylic acid hydrochloride (70 g), oxalyl chloride (25 ml), and dry benzene (250 ml) were heated together on the water bath for 2 hr. The volatile liquids were removed under reduced pressure, and the residue was heated again with oxalyl chloride (25 ml) and dry benzene (250 ml). Evaporation under reduced pressure afforded the acid chloride hydrochloride (70 g) as white prisms, mp 270° dec, sufficiently pure for further use.

*Anal.* Calcd for  $C_{22}H_{29}NO_4Cl \cdot HCl$ : Cl, 16.2. Found: Cl, 15.9, 16.5.

**6,14-endo-Etheno-7 $\alpha$ -methoxycarbonyltetrahydrothebaine (II, R = OMe).** Thebaine (5 g) and methyl acrylate (25 ml) were boiled together under reflux for 6 hr. The excess of methyl acrylate was removed under reduced pressure, and the residue was crystallized and recrystallized from methanol, when the methyl ester II (R = OMe) was obtained as white prisms, mp 148°,  $\nu_{max}$  1740  $cm^{-1}$ .

*Anal.* Calcd for  $C_{23}H_{37}NO_4$ : C, 69.5; H, 6.9. Found: C, 69.8; H, 7.0.

**Diels-Alder Addition of Acrylonitrile to Thebaine.** Thebaine (100 g) was boiled under reflux with acrylonitrile (350 ml) for 3 hr. The excess of acrylonitrile was removed by evaporation under reduced pressure, and the residue was crystallized from methanol, when the adduct (95 g) was obtained as white prisms, mp 146°, raised to 148° on recrystallization. Thin layer chromatographic studies showed the adduct to consist of two components. The adduct was boiled under reflux for 5 min in methanol solution with activated charcoal (15 g); the solution was filtered and cooled in ice. The solid separating (45 g) had mp 182–188° and consisted mainly of one compound. On recrystallization of this material, 7 $\beta$ -cyano-6,14-endo-ethenotetrahydrothebaine (35 g) was obtained as felted needles, mp 196–197°,  $\nu_{max}$  2230  $cm^{-1}$ .

*Anal.* Calcd for  $C_{22}H_{24}N_2O_3$ : C, 72.4; H, 6.7; N, 7.5. Found: C, 72.4; H, 6.8; N, 7.4.

The filtrate remaining after removal of the 7 $\beta$  nitrile following charcoal treatment of the adduct was evaporated and the residue found to contain principally the 7 $\alpha$  nitrile, which was obtained pure by partition chromatography on a Celite 545 column using heptane-methanol as the developing solvent.<sup>13</sup> Two components were eluted while monitoring the eluate at 230  $\mu$ . The more polar compound was the second component to be eluted and was recovered from the eluate as plates, mp 183–184°, on recrystallization from ethanol,  $\nu_{max}$  2230  $cm^{-1}$ . This 7 $\alpha$  nitrile was identical in mixture melting point and  $R_f$  value with the product of dehydration of the oxime of the 7 $\alpha$  aldehyde.<sup>14</sup>

*Anal.* Calcd for  $C_{22}H_{24}N_2O_3$ : C, 72.4; H, 6.7; N, 7.5. Found: C, 72.4; H, 6.9; N, 7.3.

**Preparation of Ketones from the Acid Chloride II (R = Cl).** **7 $\alpha$ -Butyryl-6,14-endo-ethenotetrahydrothebaine (II, R = *n*-Pr).** Anhydrous cadmium chloride (1.8 g) was added to a solution of *n*-propylmagnesium bromide (from 0.54 g of magnesium and 3.2 g of *n*-propyl bromide) in ether (20 ml), and the mixture was boiled under reflux for 30 min, after which the ether was removed by distillation and replaced by methylene chloride (30 ml). 7 $\alpha$ -Chlorocarbonyl-6,14-endo-ethenotetrahydrothebaine hydrochloride (5.0 g) in methylene chloride (20 ml) was added to the solution of dipropylcadmium, and the mixture was boiled under reflux for 1 hr, cooled, and then decomposed by the addition of cold 2 *N* hydrochloric acid (100 ml). The organic layer was separated, and the aqueous layer was extracted with methylene chloride (50 ml). The combined methylene chloride solutions were dried and evaporated. The residue was suspended in dilute aqueous ammonia, and the suspension was extracted with ether and the extract evaporated. The residue was dissolved in benzene and the solution passed down an alumina column, with elution subsequently with benzene. The initial eluate containing the *n*-propyl ketone II

(R = *n*-Pr) was evaporated to give a glass (3.5 g),  $\nu_{max}$  1715  $cm^{-1}$ . A portion (400 mg) of this was chromatographed in ether on thick alumina plates. The least polar band on extraction with chloroform yielded 7 $\beta$ -butyryl-6,14-endo-ethenotetrahydrothebaine (4 mg), mp 128–130°,  $\nu_{max}$  1715  $cm^{-1}$ . The immediately following band yielded 7 $\alpha$ -butyryl-6,14-endo-ethenotetrahydrothebaine (II, R = *n*-Pr) (320 mg), prisms, mp 84°,  $\nu_{max}$  1715  $cm^{-1}$ .

*Anal.* Calcd for  $C_{25}H_{31}NO_4 \cdot H_2O$ : C, 70.3; H, 7.7. Found: C, 70.6; H, 7.4.

The most polar band afforded 7 $\alpha$ ,7' $\alpha$ -bis((2-ethyl-3-hydroxy-3-propyl-1-oxopropano)-6,14-endo-ethenotetrahydrothebaine) (IX, R = Et) (40 mg),  $\nu_{max}$  1715 and 3490  $cm^{-1}$ , mp 130–133°.

*Anal.* Calcd for  $C_{36}H_{42}N_2O_8$ : C, 73.4; H, 7.6. Found: C, 73.1; H, 7.3.

By similar processes using the appropriate dialkylcadmium the following ketones were obtained: 6,14-endo-etheno-7 $\alpha$ -valeryl-tetrahydrothebaine (II, R = *n*-Bu, mp 87–90°,  $\nu_{max}$  1715  $cm^{-1}$ ). *Anal.* Calcd for  $C_{25}H_{33}NO_4$ : C, 73.6; H, 7.8. Found: C, 73.7; H, 8.0; 6,14-endo-etheno-7 $\alpha$ -isovaleryl-tetrahydrothebaine (II, R = *i*-Bu, mp 89–90°,  $\nu_{max}$  1715  $cm^{-1}$ ). *Anal.* Calcd for  $C_{27}H_{35}NO_4$ : C, 73.6; H, 7.8. Found: C, 73.4; H, 8.0; 6,14-endo-etheno-7 $\alpha$ -(4-methylpentanoyl)-tetrahydrothebaine (II, R = *i*-Am, mp 98–100°,  $\nu_{max}$  1715  $cm^{-1}$ ). *Anal.* Calcd for  $C_{27}H_{33}NO_4$ : C, 74.2; H, 8.0. Found: C, 74.2; H, 8.3.

**Preparation of Ketones from the Ester II (R = OEt).** **6,14-endo-Etheno-7 $\alpha$ -propionyl-tetrahydrothebaine (II, R = Et).** 6,14-endo-Etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (10 g) was extracted from a Soxhlet extractor into a solution of ethylmagnesium bromide, prepared from magnesium (1.67 g), ethyl bromide (7.7 g), and ether (100 ml). The mixture was boiled under reflux for 2 hr and poured into aqueous ammonium chloride. The ether layer was separated, dried, and evaporated, when a viscous gum was obtained. This was triturated with cold methanol, and the solid so obtained was collected. (This was identified as a tertiary carbinol and is described in the following paper.) The methanol solution was acidified with dilute hydrochloric acid and poured into an excess of 2 *N* aqueous sodium hydroxide to give a yellow solution containing some insoluble matter. The insoluble matter (0.4 g) was collected and recrystallized from methanol, when the 7 $\alpha$ -propionyl compound II (R = Et) was obtained as prisms, mp 42–45°, identical with the material obtained by the addition of ethyl vinyl ketone to thebaine (see above).

By similar processes, using the appropriate alkyl halide, the following ketones were prepared from the ester: 7 $\alpha$ -butyryl-6,14-endo-ethenotetrahydrothebaine (mp 84°, identical with the base obtained from the acid chloride II (R = Cl) and propylcadmium); 6,14-endo-etheno-7 $\alpha$ -oentanoyl-tetrahydrothebaine (II, R =  $C_5H_{11}$ , prisms, mp 210°, yield 6%,  $\nu_{max}$  1713  $cm^{-1}$ ). *Anal.* Calcd for  $C_{28}H_{37}NO_4$ : C, 74.4; H, 8.2. Found: C, 74.1; H, 8.4; 6,14-endo-etheno-7 $\alpha$ -vinylacetyl-tetrahydrothebaine (II, R =  $CH_2CH=CH_2$ , prisms, mp 99°, from aqueous methanol, yield 5%,  $\nu_{max}$  1710  $cm^{-1}$ ). *Anal.* Calcd for  $C_{25}H_{33}NO_4 \cdot 1.5H_2O$ : C, 69.2; H, 7.4. Found: C, 69.2; H, 7.7; 6,14-endo-etheno-7 $\alpha$ -tetrahydrofurfuryl-acetyl-tetrahydrothebaine (II, R =  $CH_2C_4H_7O$ , prisms, mp 125°, from aqueous ethanol, yield 6%,  $\nu_{max}$  1710  $cm^{-1}$ ). *Anal.* Calcd for  $C_{27}H_{33}NO_5 \cdot H_2O$ : C, 69.0; H, 7.4. Found: C, 68.7; H, 7.1; 6,14-endo-etheno-7 $\alpha$ -(3-tetrahydrofuryl)butyryl-tetrahydrothebaine (II, R =  $CH_2CH_2CH_2C_4H_7O$ , prisms, mp 98°, from aqueous methanol, yield 4%,  $\nu_{max}$  1710  $cm^{-1}$ ). *Anal.* Calcd for  $C_{29}H_{37}NO_5 \cdot 2H_2O$ : C, 67.6; H, 8.0. Found: C, 67.9; H, 8.2; 7 $\alpha$ -cyclohexylcarbonyl-6,14-endo-ethenotetrahydrothebaine (II, R =  $C_6H_{11}$ , prisms, mp 130°, from aqueous methanol, yield 7%,  $\nu_{max}$  1713  $cm^{-1}$ ). *Anal.* Calcd for  $C_{28}H_{33}NO_4 \cdot 3H_2O$ : C, 66.8; H, 8.1. Found: C, 66.9; H, 7.8).

**Preparation of Ketones from the Nitrile III.** **Nepenthone (II, R = Ph).** The Diels-Alder adduct of thebaine and acrylonitrile (mixture of 7 $\alpha$  and 7 $\beta$  forms) (10 g) in dry ether (400 ml) was slowly added to a boiling stirred solution of phenylmagnesium bromide, prepared from magnesium (1.67 g) and bromobenzene (11 g) in ether (250 ml). The mixture was boiled under reflux with stirring for 5 hr, and then poured into aqueous ammonium chloride. The ether layer was separated, dried, and evaporated, leaving a solid residue, which was heated on the water bath for 30 min with 2 *N* hydrochloric acid (150 ml). The acid solution was poured into an excess of aqueous sodium hydroxide, and the precipitated base was isolated by ether extraction. Evaporation of the extract afforded a viscous residue, which crystallized in part on trituration with methanol. The solid was collected and recrystallized, when nepenthone (1.1 g) was obtained as prisms, mp 155°, alone or mixed with an authentic specimen.

(13) We are indebted to Dr. J. J. Brown, Miss C. T. Nora, and Mr. C. Piddacks for details of this separation of the pure 7 $\alpha$  and 7 $\beta$  isomers.

*Anal.* Calcd for  $C_{28}H_{32}NO_4$ : C, 75.8; H, 6.6. Found: C, 75.6; H, 6.5.

In a similar manner, the following ketones were prepared in poor yield from *o*- and *p*-tolylmagnesium bromide: 6,14-*endo*-etheno-7 $\alpha$ -(2-methylbenzoyl)tetrahydrothebaine (prisms, mp 223°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ ). *Anal.* Calcd for  $C_{29}H_{34}NO_4$ : C, 76.1; H, 6.8. Found: C, 75.7; H, 7.1; 6,14-*endo*-etheno-7 $\alpha$ -(4-methylbenzoyl)tetrahydrothebaine (prisms, mp 196°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ ). *Anal.* Calcd for  $C_{29}H_{34}NO_4$ : C, 76.1; H, 6.8. Found: C, 75.8; H, 6.7).

7 $\alpha$ ,7' $\alpha$ -Bis(1-hydroxy-1-methyl-3-oxopropano)-6,14-*endo*-ethenotetrahydrothebaine (IX, R = H). 7 $\alpha$ -Acetyl-6,14-*endo*-ethenotetrahydrothebaine (II, R = Me) (5 g) in anhydrous benzene (20 ml) was added with vigorous stirring to a solution of anhydrous magnesium iodide (3.6 g) in ether (50 ml) and benzene (20 ml) at room temperature. A white precipitate formed almost immediately. After 15 min the mixture was decomposed by the addition of aqueous ammonium chloride. The ether-benzene layer was separated, dried, and evaporated, when a viscous gum was obtained. Chromatographic separation of this product on silica plates using a system of a 7:4:1 mixture of ethyl acetate, 2-propanol, and water showed it to contain three components in the ratio of approximately 3:6:1. Preparative plate chromatography using the same system afforded specimens of the two major components. The component with greatest  $R_f$  value (30%) was identified as 7 $\alpha$ -acetyl-6,14-*endo*-ethenotetrahydrothebaine (II, R = Me). The 60% component (intermediate  $R_f$  value) was obtained as off-white prisms, mp 150–151°, from methanol,  $\nu_{\max}$  1715 and 3490  $\text{cm}^{-1}$ , and was identified as 7 $\alpha$ ,7' $\alpha$ -bis(1-hydroxy-1-methyl-3-oxopropano)-6,14-*endo*-ethenotetrahydrothebaine (IX, R = H).

*Anal.* Calcd for  $C_{46}H_{54}N_2O_7$ : C, 72.4; H, 7.1. Found: C, 72.3; H, 7.0.

Separation of this ketol was also achieved on alumina plates using ether as solvent, and from these plates the minor component (10%) was also isolated. This has been identified as a product of rearrangement of the ketone II (R = Me) and is described in detail in another publication.<sup>7</sup>

7 $\alpha$ ,7' $\alpha$ -Bis(1-methyl-3-oxoprop-1-eno)-6,14-*endo*-ethenotetrahydrothebaine. Repeated chromatographic purification of the ketol XVI on alumina plates in ether solution led to the isolation also of a small quantity of a new base, mp 234°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ . This was also obtained by heating the ketol (70 mg) with 98–100% formic acid (1 ml) at 100° for 10 min. The solution was diluted with water, basified with ammonia, and extracted with ether, when the unsaturated ketone (50 mg) was obtained as white prisms, mp 234°, from methanol.

*Anal.* Calcd for  $C_{46}H_{54}N_2O_7$ : C, 74.2; H, 7.0. Found: C, 74.0; H, 7.1.

**Charge-Transfer Complex, Thebaine Methiodide-Benzoquinone.** Thebaine methiodide (5 g) and benzoquinone (1.5 g) were heated on the water bath in chloroform (25 ml) until separation of an orange crystalline solid began. The mixture was cooled, and the orange complex was collected (5.0 g), mp 205–206°, on rapid heating (lit.<sup>11</sup> mp 205°).

**Reduction of Complex.** A solution of sodium borohydride (0.1 g) in water (2 ml) was added to a warm stirred solution of the complex (1 g) in ethanol (15 ml). A transient violet color developed, and the solution rapidly became almost colorless. On cooling the solution, thebaine methiodide (0.6 g), mp 224°, was recovered, and on filtration and dilution of the solution with dilute ammonium chloride hydroquinone (0.12 g), mp 170°, was obtained.

Similar results were obtained when the complex in aqueous ethanol was reduced with sulfur dioxide.

**Acknowledgments.** The authors wish to thank Dr. D. E. Webster of the University of Hull, England, for the determination of nmr spectra, Mr. A. C. Young for chromatographic studies on thin and thick layer plates, and the following for experimental assistance: Mr. J. Fulstow, Mr. J. F. Saville, Mr. N. M. Scollick, Mrs. E. W. Walker, Mr. G. R. Young, and the late Mr. S. R. Duff.

## Novel Analgesics and Molecular Rearrangements in the Morphine-Thebaine Group. II.<sup>1</sup> Alcohols Derived from 6,14-*endo*-Etheno- and 6,14-*endo*-Ethanotetrahydrothebaine

K. W. Bentley, D. G. Hardy, and B. Meek

*Contribution from the Research Laboratories, Reckitt and Sons Ltd., Kingston-upon-Hull, England. Received September 26, 1966*

**Abstract:** A series of secondary and tertiary alcohols have been prepared by the reduction and reaction with Grignard reagents of the aldehyde I (R = H), the ketones I (R = Me, Et, *n*-Pr, and Ph), and their 6,14-ethano analogs. The stereospecificity of the reactions is explained. In this way analgesics of very high potency, up to 500 times that of morphine, have been obtained.

The high analgesic activity of the ketone I (R = Me) and its C-7 epimer, reported in the preceding paper, contrasts with the inactivity of the related esters I (R = OMe or OEt). The effects on the activity of further modifications of the keto group, involving removal of the electron deficiency at the carbon atom, were accordingly studied. Reduction of the ketone I (R = Me) with aluminum isopropoxide affords a product consisting of 95% of one isomer of the secondary alcohol II (R = H, R' = Me), whereas reduction with

sodium borohydride yields an approximately 1:1 mixture of this and the diastereoisomeric alcohol II (R = Me, R' = H), which was resolved into its components by preparative thin layer chromatography. Since there is more or less free rotation about the bond linking the carbonyl group to C-7, both sides of this group are almost equally accessible to attack by a hydride ion, but in the Meerwein-Ponndorf reduction, which proceeds through hydrogen transfer in a cyclic transition state,<sup>2</sup> steric hindrance in the transition state results in the preferential transfer of hydrogen to one

side of the carbonyl group. The examination of models of such a six-membered transition state (see below) shows that steric hindrance is least in the arrangement that leads to the alcohol II ( $R = H$ ,  $R' = Me$ ).

An excess of methylmagnesium iodide converts the ketone I ( $R = Me$ ) in high yield into the tertiary alcohol II ( $R = R' = Me$ ), which is also readily prepared from the esters I ( $R = OMe$  or  $OEt$ ), and the nmr spectrum of this alcohol shows that the stereochemical disposition of groups at C-7 is the same as that in the parent ketone.<sup>3a</sup> The tertiary alcohol epimeric at C-7 with II ( $R = R' = Me$ ) was prepared in the same way from the  $7\beta$  isomer of the ketone I ( $R = Me$ ). The carbinols prepared in this way were all found to be potent analgesics. Accordingly, the variation in analgesic activity within a series of alcohols of general structure II was studied, and during the course of this work many compounds were obtained with analgesic activities never previously approached in the morphine series, in which hitherto the most active members have been 14-acetoxydihydrocodeinone<sup>4</sup> and 5-methyldihydromorphinone,<sup>5</sup> both of which are about 12 times as active as morphine.

The alcohols of general structure II were prepared by the action of Grignard reagents or lithium alkyls on the aldehyde I ( $R = H$ ), the ketones I ( $R = Me$ ,  $Et$ ,  $n$ -Pr, and  $Ph$ ), and the ester I ( $R = OEt$ ). The reactions of the ketones I with Grignard reagents  $R'MgX$  are generally complex and lead to the formation of a number of products resulting from the following processes: (a) normal Grignard reaction with  $R'MgX$  to give the tertiary carbinol II (major reaction); (b) normal Grignard reaction with  $R'MgX$  to give the tertiary alcohol diastereoisomeric with II (minor reaction); (c) Grignard reduction where possible, *i.e.*, when  $R'$  contains a  $\beta$ -hydrogen atom, to give the secondary alcohol II ( $R' = H$ ) (major reaction in many

cases);<sup>6a</sup> (d) Grignard reduction to give the diastereoisomeric secondary alcohol II ( $R = H$ ) (minor reaction); and (e) base-catalyzed rearrangement of the ketone followed by Grignard reaction at the carbonyl group (minor reaction). Of these processes the base-catalyzed rearrangement is of minor importance and will be discussed in detail together with other topics in a subsequent communication.<sup>6b</sup>

The normal Grignard reaction in this series shows a remarkably high degree of stereoselectivity, and in those cases in which Grignard reduction does not compete with the normal reaction a high yield of an almost pure diastereoisomer of the tertiary carbinol is obtained. For example, the ketone I ( $R = Me$ ) with phenylmagnesium bromide afforded almost entirely the alcohol II ( $R = Me$ ,  $R' = Ph$ ), whereas the diastereoisomeric alcohol II ( $R = Ph$ ,  $R' = Me$ ) was the almost sole product of the action of methylmagnesium iodide on the phenyl ketone I ( $R = Ph$ ). The presence of a trace of the second isomer in the product in each case was demonstrated by thin layer chromatography. The stereochemical assignments of structures to these isomeric carbinols, at first tentatively made after a study of models, were rigorously confirmed by nmr spectroscopic studies.<sup>3a</sup>

Similarly the tertiary carbinol II ( $R = Me$ ,  $R' = n$ -Pr), resulting from the normal Grignard reaction of  $n$ -propylmagnesium iodide with the methyl ketone I ( $R = Me$ ), is diastereoisomeric with the principal product II ( $R = n$ -Pr,  $R' = Me$ ) of the interaction of methylmagnesium iodide and the  $n$ -propyl ketone I ( $R = n$ -Pr). The seat of the isomerism was clearly shown in this case to be the alcoholic group since both carbinols were dehydrated to the same olefin III, which gave propionaldehyde on ozonolysis.<sup>7</sup> The structure of the carbinol II ( $R = Me$ ,  $R' = n$ -Pr) has been confirmed by X-ray crystallographic analysis of the hydrobromide.<sup>3b</sup>

Grignard reduction is, where possible, a process seriously competitive with the normal Grignard reaction, and in some cases accounts for up to 30% of the total product. Like the normal reaction, it shows a remarkably high degree of stereoselectivity, and the product consists almost entirely of the alcohol II ( $R' = H$ ), though the presence of about 5% of the diastereoisomer II ( $R = H$ ) can be detected on thin layer chromatographic plates. Both the Grignard and Meerwein-Ponndorf reduction processes are generally believed to proceed by hydrogen transfer in similarly constituted transition states,<sup>2,8</sup> IV and V, and might thus in the case of the ketone I ( $R = Me$ ) be expected to lead to the same product. This expectation is not borne out in practice.

Grignard reduction of the ketone with  $n$ -propyl- or isobutylmagnesium halides affords the secondary alcohol diastereoisomeric with that obtained in the Meerwein-Ponndorf reduction, and identical with the

second component of the product of reduction of the ketone with sodium borohydride. If the Meerwein-Pondorff reduction leads, as postulated above, to the alcohol II ( $R = H$ ,  $R' = Me$ ), the product of Grignard reduction must have the structure II ( $R = Me$ ,  $R' = H$ ), and these structural assignments have been confirmed in the following way. The Meerwein-Pondorff reaction product in chloroform solution shows hydroxyl absorption at  $3504\text{ cm}^{-1}$ , indicating strong hydrogen bonding between the hydroxyl and the spatially proximate C-6 methoxyl group, which results in an arrangement involving disposition of the hydrogen atom in the carbinol system of the alcohol II ( $R = H$ ,  $R' = Me$ ) "downward" toward the 6,14-etheno bridge. In agreement with such a representation, in which steric hindrance of the etheno bridge is minimal, this alcohol is very readily hydrogenated at room temperature and pressure. Hydrogen bonding of a similar kind in the isomeric alcohol II ( $R = Me$ ,  $R' = H$ ) would, however, involve disposition of the larger  $CH_3$  group "downward" toward the etheno bridge, and this would be expected to result in some hindrance to hydrogenation of the bridge and also to a weakening of the hydrogen bond or even to the establishment of an alternative arrangement with a weak bond between the hydroxyl group and the  $\pi$  orbitals of the etheno bridge. In agreement with this, the Grignard reduction product of the ketone I ( $R = Me$ ) is resistant to hydrogenation at room temperature, and shows hydroxyl absorption at  $3540\text{ cm}^{-1}$  (weaker hydrogen bond than in the isomeric carbinol) and also at  $3605\text{ cm}^{-1}$  (feeble bond to the etheno bridge).

Thus, both Grignard reaction with and Grignard reduction of the ketone I ( $R = Me$ ) afford products belonging to the same stereochemical series II ( $R = Me$ ). This asymmetric induction may be explained on the basis of a model similar to those outlined by Cram and his co-workers.<sup>9</sup> If the Cram five-membered transition state is replaced in this series by a six-membered intermediate in which a complex is formed by coordination of the magnesium atom with oxygen atoms of both C-7 carbonyl and C-6 methoxyl groups (thus completing the outer electron shell of the magnesium), then an inspection of models shows that "top-side" approach of the group  $R'$  to the carbonyl carbon, as depicted in VI, leading to VII is much less hindered than approach from below (the vicinity of the 6,14-etheno bridge). In the same complex, if the group  $R'$  is one in which  $\beta$ -hydrogen transfer can occur then Grignard reduction (VIII) would lead to alcohol IX [identical with the complete structure II ( $R = Me$ ,  $R' = H$ )] belonging to the same stereochemical series as the products of the normal reaction.

In the Meerwein-Pondorff reduction, however, the aluminium atom can complete its valency shell by co-

ordination with the carbonyl oxygen atom alone, and the establishment of a more rigid cyclic arrangement involving the C-6 methoxyl group is not necessary. In such a case, free rotation about the carbonyl-C-7 bond is still possible and hydrogen transfer in the complex would be expected to occur with the groups in the disposition involving least steric hindrance. This arrangement is that in which the coordinated carbonyl group is most remote from the group with the greatest effective size, namely the C-6 methoxyl group. This arrangement is shown in part structure X, which is a Newman projection of part of the ketone I ( $R = Me$ ) looking along the line of the carbonyl-C-7 bond, and least hindered hydrogen transfer to the carbonyl group would occur as shown, from above, to give the secondary alcohol XI which is identical with XII. This alcohol is diastereoisomeric with that obtained by Grignard reduction, and is represented in full by structure II ( $R = H$ ,  $R' = Me$ ).

The reaction of the ketone I ( $R = Me$ ) with lithium alkyls involves, in the cases studied, more base-catalyzed rearrangement than does the reaction with Grignard reagents, but this still remains a minor side reaction ( $<10\%$ ), and the formation of tertiary carbinol is somewhat less stereoselective. Secondary alcohol formation is not observed, however, and in those cases in which Grignard reduction is troublesome the use of the corresponding lithium alkyl is to be preferred.

<sup>a</sup> Morphine = 1. <sup>b</sup> Hydrobromide. <sup>c</sup> Bitartrate.

The alcohols of general structure II prepared in this way are listed, together with their analgesic potencies, in Table I. The analgesic activities were determined by the tail pressure method in rats, with administration of the compounds usually as their hydrochlorides in aqueous solution by the subcutaneous route, and this

work will be reported in detail elsewhere, together with the results of other pharmacological studies.<sup>10</sup> The highest activities are observed in those alcohols in which there is a moderate disparity in size between R and R',

(10) Some details are briefly given by R. E. Lister, *J. Pharm. Pharmacol.*, 16, 364 (1964).

and in homologous series in which the group R remains constants as a hydrogen atom or a methyl group peak activity is reached when R' has a size equivalent to that of a three to five carbon chain, and further lengthening of the chain results in a steady decrease in activity. The preferred constant substituent R is a methyl group, and the most potent analgesic in this series is the alcohol II (R = Me, R' = CH<sub>2</sub>CH<sub>2</sub>Ph).

The alcoholic hydroxyl group of the secondary alcohols was readily esterified, but this modification has little effect on the analgesic potency. The tertiary alcohols, however, are very resistant to esterification. The two diastereoisomeric secondary alcohols II (R = H, R' = Me and R = Me, R' = H) were esterified with phenylglyoxalyl chloride and, following Prelog's method,<sup>11</sup> the resulting esters were treated with methylmagnesium iodide and the products hydrolyzed to atrolactic acid. With the alcohol II (R = H, R' = Me), the three conformations of the phenylglyoxalyl ester are XIII, XIV, and XV, in which  $\theta$  represents the tetrahydrothebaine unit, and in these the size of groups is in the order  $\theta > \text{Me} > \text{H}$  and, as in the cases studied by Prelog, attack by the Grignard reagent on XIII would be from below and on XIV and XV would be from above. However, the examination of models of

XIII

XIV

XV

XVI

XVII

XVIII

these three conformations reveals that nonbonded interactions are very much less in the form represented by XIII than in the other two, and the ester would be expected to adopt predominantly this form, attack of which by the Grignard reagent would lead, after hydrolysis, to an excess of (+)-atrolactic acid. With the ester from the diastereoisomeric alcohol II (R = Me, R' = H) the conformation XVI would be expected to be heavily favored over XVII and XVIII, and the same process with this ester would be expected to lead to an excess of (–)-atrolactic acid. In this event this sequence of reactions on the alcohol obtained by Meerwein-Ponndorff reduction of the ketone I (R = Me) gave atrolactic acid,  $[\alpha]^{20D} +4.8^\circ$ , whereas the product of Grignard reduction of the ketone in the same way afforded atrolactic acid,  $[\alpha]^{20D} -5.4^\circ$ , and these results support the structures assigned above to these bases.

O-Alkylation of the tertiary alcohols was also very difficult, but the base II (R = R' = Me) was methylated with potassamide and methyl iodide in liquid ammonia to its methyl ether. Other attempted alkylations of this

base and the methylation of other tertiary alcohols in the series proved unsuccessful.

Catalytic reduction of the tertiary alcohols was in all cases achieved only at elevated temperature and pressure. Hydrogen bonding between the hydroxyl and C-6 methoxyl groups results in conformations in which one or the other of the alkyl groups R and R' in structure II is disposed in the direction of the 6,14-etheno bridge, with consequent hindrance of the approach of this bridge to the catalyst surface. Reduction is achieved over Raney nickel catalyst at 160–170° (200 atm) to give bases of general structure XIX. These 6,14-etheno alcohols are also preparable from the 6,14-ethano ketone XX which is obtained from the etheno ketone I (R = Me) by reduction under milder conditions. The effect of the COCH<sub>3</sub> group in the ketone I (R = Me) in shielding the etheno bridge is much less than the effect of the alcoholic group in the hydrogen-bonded alcohols II, and since the shielding effect on the etheno bridge of the smaller CHO group is even less than that of the COCH<sub>3</sub> group, the aldehyde I (R = H) can be reduced under even milder conditions. In the 7 $\beta$ -acetyl compound, the COCH<sub>3</sub> group is disposed on the side of the molecule opposite to the etheno bridge, hydrogenation of which is accordingly unhindered, and this base can be rapidly reduced at room temperature. The Grignard reaction with the 6,14-ethano ketone XX in general follows the same pattern as that with the etheno analog II (R = Me), giving rise to tertiary carbinol XIX, secondary carbinol as a result of Grignard reduction, and base-catalyzed rearrangement. Base-catalyzed rearrangement is generally more important in this than in the etheno series, and on occasions accounts for up to 30% of the product.<sup>6b</sup> The normal Grignard reaction displays the same stereospecificity as in the 6,14-etheno series. The 6,14-ethano alcohols XIX prepared by these methods are listed in Table II.

\* Morphine = 1.

dation of the quaternary salts proceeded very readily to give the expected methine bases XXI.

**Nomenclature.** The systematic nomenclature for the bases in this series, based on the 6,14-*endo*-ethenotetrahydrothebaine system, is cumbersome and, since many degradation and rearrangement products of thebaine, codeine, and morphine already have simple trivial names, a simpler system, based on a trivial name for a key intermediate, would be an advantage. The trivial name nepenthone was assigned to the phenyl ketone I (R = Ph) in order to facilitate the naming of derivatives. The intermediates that have been most widely used in this work are the aldehyde I (R = H) and the ketones I (R = Me and Ph) and of these the ketone I (R = Me) is much the most active as an analgesic and gives rise to a very wide series of alcohols of structure II (R = Me) of high activity. These alcohols are more easily prepared and of much greater pharmacological interest than the corresponding bases II (R ≠ Me). Accordingly, a trivial name has been assigned to the ketone I (R = Me). This ketone is the adduct of thebaine and methyl vinyl ketone and by a suitable selection of syllables from the names of these compounds the name *thevinone* emerges for the ketone I (R = Me). The related secondary alcohol II (R = Me, R' = H) then becomes *thevinol*, and the other bases in the series II (R = Me), being obviously homolog of II (R = Me, R' = H), may be named as alkylthevinols, e.g., the alcohol II (R = Me, R' = *n*-Pr) becomes *propylthevinol* and II (R = Me, R' = CH<sub>2</sub>CH<sub>2</sub>-Ph) becomes *phenethylthevinol*.

As will be seen in the following paper, most of the alcohols of the series II have been demethylated to phenolic 3-hydroxy analogs, and bases of this series corresponding to those of structure II (R = Me), being derivatives of tetrahydrooripavine rather than tetrahydrothebaine, can be termed alkylorvinols, e.g., the 3-hydroxy analog of the base II (R = Me, R' = cyclohexyl) would be *cyclohexylorvinol*.

The acid I (R = OH), being an oxidized form of thevinone, can be named *thevinoic acid* and the ester I (R = OEt) then becomes *ethyl thevinoate* and the acid chloride I (R = Cl) *thevinoyl chloride*. (The term thevinic acid is avoided as this leads to the acid chloride being named thevinyl chloride, which should be reserved for the halide corresponding to thevinol.)

Since a series of 6,14-ethano alcohols XIX derived from the ketone XX is known, this last base can be termed *hydrothevinone* and the alcohols thus become *alkylhydrothevinols*, or hydroorvinols after O-demethylation. Relatively simple extensions of this nomenclature permit rational names to be assigned to other bases resulting from transformations of the ketone I (R = Me) and the alcohols II (R = Me), and these will be discussed where necessary in subsequent publications.

### Experimental Section

Examples only of representative Grignard reactions and reductions are given in this section to show the general processes used.

**7α-(1-Hydroxy-1-methylethyl)-6,14-*endo*-ethenotetrahydrothebaine (19-Methylthevinol) (II, R = R' = Me).** a. A solution of 7α-acetyl-6,14-*endo*-ethenotetrahydrothebaine (thevinone) (I, R = Me) (10 g) in dry ether (500 ml) or in dry benzene (50 ml) was added slowly with vigorous stirring to a refluxing solution of methylmagnesium iodide, prepared from magnesium (1.67 g) and methyl iodide (9.9 g) in ether (100 ml), and the mixture was stirred and heated under reflux for 2 hr. The mixture was then shaken with aqueous ammonium chloride, and the organic layer was separated, dried, and evaporated, leaving a crystalline base (10 g), which was recrystallized from ethanol. The base was obtained in this way as plates, mp 166°.

*Anal.* Calcd for C<sub>26</sub>H<sub>33</sub>NO<sub>4</sub>: C, 72.5; H, 7.9. Found: C, 72.5; H, 7.7.

b. 6,14-*endo*-Etheno-7α-ethoxycarbonyltetrahydrothebaine (ethyl thevinoate) (I, R = OEt) (10 g) was extracted from a Soxhlet extractor into a boiling stirred solution of methylmagnesium iodide (from 1.67 g of magnesium and 9.9 g of methyl iodide) in ether (100 ml). The mixture was boiled under reflux for 3 hr, and the product isolated as in a above, when it was obtained (9.8 g) as white prisms, mp 166°, alone or mixed with material prepared from the ketone.

**7β-(1-Hydroxy-1-methylethyl)-6,14-*endo*-ethenotetrahydrothebaine (19-Methyl-β-thevinol) (C-7 Epimer of II, R = R' = Me).** a. A solution of 7β-acetyl-6,14-*endo*-ethenotetrahydrothebaine (0.5 g) in ether (100 ml) was added to a stirred refluxing solution of methylmagnesium iodide (from 0.17 g of magnesium and 1 g of methyl iodide), and the mixture was boiled under reflux for 1 hr. Isolation of the product in the usual way afforded a mixture of two nonketonic products. These were separated on thick alumina plates, and the base, having the greater R<sub>f</sub> value, was obtained as prisms, mp 190°, on recrystallization from ethanol. It was identified as the alcohol epimeric at C-7 with II (R = R' = Me) by its nmr and infrared spectra, which were very similar to but not identical with those of II (R = R' = Me).

*Anal.* Calcd for C<sub>26</sub>H<sub>33</sub>NO<sub>4</sub>: C, 72.5; H, 7.9. Found: C, 72.5; H, 7.7.

The second product, of lower R<sub>f</sub> value, was phenolic and has been identified as a product of base-catalyzed rearrangement of the

ketone followed by Grignard reaction and is described in I in a later paper.<sup>6b</sup>

**duction of 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (Thebe) (I, R = Me).** a. The ketone I (R = Me) (10 g) was boiled aluminum isopropoxide (10 g) and 2-propanol (100 ml) with distillation of the solvent through a 36-plate fractionating column until the distillate no longer gave a precipitate with a solution of 4-dinitrophenylhydrazine in aqueous hydrochloric acid. On completion of the reaction, the mixture was evaporated to small bulk poured into dilute hydrochloric acid. The acid solution was treated with potassium sodium tartrate and basified with ammonia, and the precipitated base was isolated by ether extraction, the carbinol II (R = H, R' = Me) was obtained as a viscous material that was crystallized from aqueous methanol, being then obtained as white prisms, mp 78–80°, raised to 82° by further recrystallization from aqueous methanol or ether at low temperatures.

*Anal.* Calcd for C<sub>23</sub>H<sub>29</sub>NO<sub>4</sub>: C, 72.1; H, 7.6. Found: C, 72.1; H, 7.5.

Thin layer chromatographic studies showed that the base, mp 78–80°, first obtained contained about 5% of the isomeric carbinol (R = Me, R' = H), which is the main product of Grignard reaction of the ketone.

The O-formyl ester was prepared by heating the alcohol with 100% formic acid at 100° for 1 hr and was obtained as plates, mp 10–12°, from aqueous methanol.

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>5</sub>: C, 70.1; H, 7.1. Found: C, 70.1; H, 7.2.

The O-acetyl ester, prepared from the alcohol and acetic anhydride and pyridine, was obtained as plates, mp 170°, from aqueous ethanol.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>5</sub>: C, 70.7; H, 7.3. Found: C, 70.7; H, 7.5.

The ketone I (R = Me) (10 g) was boiled under reflux in ethanol (50 ml) with sodium borohydride (1 g) for 30 min. The solution was concentrated by evaporation and poured into water. The precipitated base was isolated by ether extraction, when it was obtained as a viscous gum, shown by thin layer chromatography to consist of an approximately 1:1 mixture of the products of the Wein-Pondorff and Grignard reduction of the ketone.

**7 $\alpha$ -(1-*R*)-Hydroxy-1-methylbutyl-6,14-endo-ethenotetrahydrothebaine (19-Propylthevinol) (II, R = Me, R' = *n*-Pr)** and Grignard reduction of the ketone I (R = CH<sub>3</sub>). 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (I, R = CH<sub>3</sub>) (50 g) in dry benzene (250 ml) was added to a vigorously stirred refluxing solution of *n*-propylmagnesium iodide (from 8.35 g of magnesium and 58.5 g of 1-iodopropane) in ether (500 ml), and the mixture was boiled under reflux for 2 hr.

The product, isolated in the usual way, was a viscous gum which crystallized on trituration with methanol (100 ml). The solid was collected and recrystallized from ethanol, when the alcohol (R = Me, R' = *n*-Pr) was obtained as white prisms, mp 176° (lit.<sup>1</sup> 178°).

*Anal.* Calcd for C<sub>26</sub>H<sub>33</sub>NO<sub>4</sub>: C, 73.3; H, 8.2. Found: C, 73.3; H, 8.2.

The mother liquors were diluted with methanol (50 ml) and water added until precipitation of gummy material began. The solution was allowed to stand for 15 min, decanted from the gummy material, and then kept in the refrigerator, when the Grignard reaction product, 7 $\alpha$ -(1-*S*)-hydroxyethyl-6,14-endo-ethenotetrahydrothebaine (thevinol) (II, R = Me, R' = H) (12 g) was obtained as needles, mp 76–78°, raised to 81° on recrystallization from aqueous methanol.

*Anal.* Calcd for C<sub>23</sub>H<sub>29</sub>NO<sub>4</sub>: C, 72.1; H, 7.6. Found: C, 72.1; H, 8.0.

The O-formyl ester, prepared by heating the secondary alcohol with 98–100% formic acid at 100° for 1 hr, was obtained as prisms, mp 48°, from aqueous methanol.

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>5</sub>·0.5H<sub>2</sub>O: C, 68.6; H, 7.2. Found: C, 68.7; H, 7.3.

The O-acetyl ester, prepared from the alcohol, acetic anhydride, and pyridine, was obtained as prisms, mp 120°, from aqueous ethanol.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>5</sub>: C, 70.7; H, 7.3. Found: C, 70.7; H, 7.5.

A third base has been isolated from the residues of separation of the Grignard reduction product. This was a phenol, mp 201–202°, and is a product of base-catalyzed rearrangement of the parent ketone followed by normal Grignard reaction with propylmagnesium iodide; it is described fully in a later paper.<sup>6b</sup>

**7 $\alpha$ -(1-*S*)-Hydroxy-1-methylbutyl-6,14-endo-ethenotetrahydrothebaine (II, R = *n*-Pr, R' = Me).** 7 $\alpha$ -Butyryl-6,14-endo-ethenotetrahydrothebaine (I, R = *n*-Pr) (15 g) in ether (500 ml) was added

to a stirred solution of methylmagnesium iodide (from 2 g of magnesium and 6 ml of methyl iodide) in ether (150 ml), and the mixture was boiled under reflux for 1 hr. Isolation of the product in the usual way afforded 10.1 g of a base containing about 10% of the alcohol II (R = Me, R' = *n*-Pr). After several recrystallizations from methanol the alcohol II (R = *n*-Pr, R' = Me) was obtained almost pure, as prisms, mp 144–145°, and a pure specimen, mp 148–149°, for spectral studies was obtained by layer chromatographic separation on alumina.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>4</sub>: C, 73.3; H, 8.2. Found: C, 73.2; H, 8.4.

**7 $\alpha$ -(1-*R*)-Hydroxy-1-methylpropyl-6,14-endo-ethenotetrahydrothebaine (19-ethylthevinol) (II, R = Me, R' = Et)** was obtained by the above general method from the ketone I (R = Me) and ethylmagnesium bromide as prisms, mp 74°, with resolidification and final melting at 135°.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>4</sub>: C, 73.1; H, 8.1. Found: C, 72.9; H, 8.1.

It was also obtained by the reduction of the vinylcarbinol II (R = Me, R' = CH=CH<sub>2</sub>); see below.

**7 $\alpha$ -(1-*S*)-Hydroxy-1-methylpropyl-6,14-endo-ethenotetrahydrothebaine (II, R = Et, R' = Me)** was prepared by the general method from the ketone I (R = Et) and methylmagnesium iodide, when it was obtained as prisms, mp 165°.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>4</sub>: C, 73.1; H, 8.1. Found: C, 72.9; H, 8.2.

It was also obtained by the reduction of the acetylenic carbinol II (R = C $\equiv$ CH, R' = Me); see below.

**7 $\alpha$ -(1-*R*)-Hydroxy-1-methylprop-2-enyl-6,14-endo-ethenotetrahydrothebaine (19-Vinylthevinol) (II, R = Me, R' = CH=CH<sub>2</sub>).** A solution of 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine (I, R = Me) (19 g) in dry tetrahydrofuran (30 ml) was added to a refluxing solution of vinylmagnesium bromide (from 3.0 g of magnesium and 13.4 g of vinyl bromide) in tetrahydrofuran, and the mixture was boiled under reflux for 2 hr. Saturated aqueous ammonium chloride was added, and the organic layer was separated, dried, and evaporated. The residual brown gum was crystallized from methanol when the alcohol was obtained as white prisms, mp 155°.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>4</sub>: C, 73.3; H, 7.6. Found: C, 73.3; H, 7.6.

**Reduction.** The alcohol II (R = Me, R' = CH=CH<sub>2</sub>) (5 g) in ethanol (100 ml) was shaken under hydrogen at 22° (750 mm) in the presence of platinum oxide (100 mg). Hydrogen (300 ml) was absorbed over 30 min, after which reduction ceased. Filtration and evaporation of the solution gave 5.0 g of material which on crystallization from ethanol gave prisms, mp 74 and 135°, unaltered on mixing with the alcohol II (R = Me, R' = Et), obtained from the action of ethylmagnesium bromide on the ketone I (R = Me). The infrared spectra and chromatographic behavior on alumina plates of the bases from the two sources were also identical.

**7 $\alpha$ -(1-*S*)-Hydroxy-1-methylprop-2-ynyl-6,14-endo-ethenotetrahydrothebaine (19-Ethynylthevinol) (II, R = C $\equiv$ CH, R' = Me).** 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (I, R = Me) (38 g) in dry tetrahydrofuran (200 ml) was added with stirring to a solution of lithium acetylide-ethylenediamine complex (10 g) under an atmosphere of argon. The mixture was stirred at 35° for 3 hr and poured into water (200 ml). The mixture was extracted three times with ether, and the combined extracts were dried and evaporated. The residue crystallized in part on trituration with methanol (20 ml), and the solid (10.5 g) was collected and recrystallized from methanol when the alcohol II (R = C $\equiv$ CH, R' = Me) was obtained as prisms, mp 185–186°.

*Anal.* Calcd for C<sub>25</sub>H<sub>29</sub>NO<sub>4</sub>: C, 73.7; H, 7.1. Found: C, 73.6; H, 7.2.

A further 4.1 g of material, mp 183–184°, was obtained on concentration of the mother liquors. Final evaporation of these liquors afforded a gum shown by thin layer chromatography to consist of an approximately 1:1 mixture of the above base and a second compound, presumably the diastereoisomeric alcohol II (R = Me, R' = C $\equiv$ CH), since the infrared spectrum of the mixture was almost identical with that of the pure base, mp 185–186°.

**Reduction.** The acetylenic alcohol II (R = C $\equiv$ CH, R' = Me) (4.0 g) was hydrogenated over platinum oxide (100 mg) in ethanol at 22° (760 mm). Hydrogen (449 ml, 2 moles) was absorbed over 20 min, and isolation of the product afforded the alcohol II (R = Et, R' = Me), mp 165°, identical in melting point, mixture melting point, infrared absorption, and *R<sub>f</sub>* value with the product of the action of methylmagnesium iodide on the ketone I (R = Et).

**Study of the Stereochemistry at C-19 of the Alcohols II (R = H, R' = Me and R = Me, R' = H).** A solution of 7 $\alpha$ -(1-*R*)-hydroxy-

ethyl)-6,14-*endo*-ethenotetrahydrothebaine (II, R = H, R' = Me) (5 g) and phenylglyoxalyl chloride (6 g) in pyridine (12 ml) was kept at room temperature overnight. Ice water was then added until separation of solid matter occurred. The solid was isolated by ether extraction, and the viscous gum so obtained was crystallized by trituration with methanol. The solid was collected (3.5 g) and recrystallized from methanol when the phenylglyoxalyl ester was obtained as off-white plates, mp 206°.

*Anal.* Calcd for  $C_{21}H_{23}NO_6 \cdot H_2O$ : C, 69.85; H, 6.7. Found: C, 70.0; H, 7.0.

A solution of methylmagnesium iodide (from 0.95 g of magnesium and 25 ml of methyl iodide) in ether (30 ml) was added to a solution of the phenylglyoxalyl ester (5 g) in dry benzene (100 ml), and the mixture was kept at room temperature for 3 hr and then boiled under reflux for 3 hr. The mixture was poured into aqueous ammonium chloride; the organic layer was separated and the aqueous layer extracted twice with chloroform. The combined ether-benzene and chloroform solutions were evaporated, and the residue was boiled under reflux with 5% methanolic potassium hydroxide (200 ml) for 5 hr. Most of the methanol was evaporated, and the mixture was diluted with water (200 ml) and extracted four times with ether to remove the organic base. The aqueous layer was acidified with hydrochloric acid and extracted continuously with ether for 3 days. The ether extract on evaporation afforded a gum from which atrolactic acid, mp 114–115°,  $[\alpha]_D^{20} +4.8^\circ$ , was obtained as white needles on extraction with light petroleum (bp 80–100°).

Repetition of the above reactions using 7 $\alpha$ -(1-(*S*)-hydroxyethyl)-6,14-*endo*-ethenotetrahydrothebaine (II, R = Me, R' = H) as starting material afforded the phenylglyoxalyl ester as prisms, mp 96 and 170°, and atrolactic acid, mp 114–115°,  $[\alpha]_D^{20} -5.4^\circ$ .

*Anal.* Calcd for  $C_{21}H_{23}NO_6 \cdot H_2O$ : C, 69.85; H, 6.7. Found: C, 70.2; H, 7.0.

**7 $\alpha$ -Acetyl-6,14-*endo*-ethanotetrahydrothebaine (Dihydrothevinone) (XX).** 7 $\alpha$ -Acetyl-6,14-*endo*-ethenotetrahydrothebaine (I, R = Me) (5 g) in ethanol (200 ml) was shaken with 10% palladium on charcoal (0.5 g) under hydrogen at 58 psi at 50° for 10 hr. The mixture was filtered from the catalyst and evaporated. The residue was crystallized from ethanol when the 6,14-*endo*-ethano-7 $\alpha$ -ketone (3.8 g) was obtained as white prisms, mp 134–136°,  $\nu_{max}$  1710  $cm^{-1}$ .

*Anal.* Calcd for  $C_{23}H_{25}NO_4$ : C, 72.0; H, 7.6. Found: C, 71.6; H, 7.6.

**7 $\beta$ -Acetyl-6,14-*endo*-ethanotetrahydrothebaine ( $\beta$ -Dihydrothevinone) (C-7 Epimer of XX).** 7 $\beta$ -Acetyl-6,14-*endo*-ethenotetrahydrothebaine (0.38 g) was hydrogenated over 10% palladium on charcoal (0.20 g) in ethanol (100 ml) at 22° (755 mm). Hydrogen (22 ml) was absorbed over 7 min. The solution was filtered and evaporated, and the residue was crystallized from ethanol when the 6,14-ethano-7 $\beta$ -ketone was obtained as prisms, mp 166°.

*Anal.* Calcd for  $C_{23}H_{25}NO_4$ : C, 72.0; H, 7.6. Found: C, 71.8; H, 7.6.

**6,14-*endo*-Ethano-7 $\alpha$ -formyltetrahydrothebaine (XX, CH<sub>3</sub> = H).** 6,14-*endo*-Etheno-7 $\alpha$ -formyltetrahydrothebaine (I, R = H) (1.84 g) was hydrogenated over 10% palladium on charcoal (0.3 g) in ethanol (50 ml) at 22° (760 mm). Hydrogen (112 ml) was absorbed over 2.5 hr. The isolated product was crystallized from ethanol when the 6,14-*endo*-ethano-7 $\alpha$ -aldehyde was obtained as prisms, mp 98°,  $\nu_{max}$  1740  $cm^{-1}$ .

*Anal.* Calcd for  $C_{22}H_{27}NO_4$ : C, 71.5; H, 7.4. Found: C, 71.2; H, 7.2.

**6,14-*endo*-Ethano-7 $\alpha$ -(1-(*R*)-hydroxyethyl)tetrahydrothebaine (XIX, R = H, R' = Me).** 6,14-*endo*-Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-

ethyl)tetrahydrothebaine (II, R = H, R' = Me) (25 g) (from the Meerwein-Ponndorf reduction of the ketone I, R = Me) was hydrogenated at 22° (760 mm) in ethanol (100 ml) over 10% palladium on charcoal (1 g). Hydrogen (1500 ml) was absorbed over 30 min. The product was isolated as prisms, mp 49–51°, from aqueous methanol.

*Anal.* Calcd for  $C_{23}H_{27}NO_4$ : C, 71.6; H, 8.1. Found: C, 71.5; H, 8.2.

The O-*p*-toluenesulfonate was obtained as prisms, mp 157°, from benzene-methanol.

*Anal.* Calcd for  $C_{20}H_{27}NO_6S \cdot 0.5H_2O$ : C, 65.6; H, 7.0; S, 5.8. Found: C, 65.3; H, 7.0; S, 5.7.

The diastereoisomeric alcohol II (R = Me, R' = H), from the Grignard reduction of the ketone I (R = Me), was resistant to hydrogenation under the above conditions and at temperatures up to 60°.

**6,14-*endo*-Ethano-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (Dihydro-19-methylthevinol) (XIX, R = R' = Me).** a. 6,14-*endo*-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (II, R = R' = Me) (40 g) was hydrogenated in ethanol (300 ml) over W4 Raney nickel (10 g) at 160–165° (164–182 atm) for 4 hr. The solution was filtered and concentrated to yield the 6,14-ethano alcohol as white prisms, mp 142°, after recrystallization from ethanol.

*Anal.* Calcd for  $C_{24}H_{29}NO_4$ : C, 72.2; H, 8.3; N, 3.5. Found: C, 71.8; H, 8.2; N, 3.5.

b. The same base was obtained by the action of methylmagnesium iodide (from 0.83 g of magnesium and 5.2 g of methyl iodide) on 7 $\alpha$ -acetyl-6,14-*endo*-ethanotetrahydrothebaine (dihydrothevinone) (4.8 g) in ether solution.

**Hofman Degradation of the Alcohols II (R = Me, R' = *n*-Pr and R = Me, R' = Ph).** 19-Propylthevinol (II, R = Me, R' = *n*-Pr) and 19-phenylthevinol (II, R = Me, R' = Ph) (2 g) were separately boiled under reflux with methyl iodide (10 ml) and acetone (20 ml) for 7 days. The solvent was evaporated, and the residue was recrystallized from ethanol to give 19-propylthevinol methiodide (white prisms, mp 188–190°. *Anal.* Calcd for  $C_{27}H_{35}NO_4 \cdot 0.5H_2O$ : C, 56.3; H, 6.8. Found: C, 56.4; H, 5.8) and 19-phenylthevinol methiodide (white prisms, mp 194–196°. *Anal.* Calcd for  $C_{30}H_{33}NO_4 \cdot 0.5H_2O$ : C, 59.0; H, 6.1. Found: C, 58.7; H, 6.1).

The methiodides (1 g) were degraded by boiling under reflux with 20% aqueous potassium hydroxide for 15 min. The solution was diluted and the product collected at the pump and recrystallized from aqueous ethanol to give 19-propylthevinol methine (XXI, R' = *n*-Pr; white needles, mp 90–95°,  $\lambda_{max}$  230, 279, 308, 318  $m\mu$  ( $\epsilon_{max}$  12,000, 7000, 3000, 2300). *Anal.* Calcd for  $C_{28}H_{37}NO_4 \cdot H_2O$ : C, 70.9; H, 8.5. # Novel Analgesics and Molecular Rearrangements in the Morphine-Thebaine Group. III.<sup>1</sup> Alcohols of the 6,14-*endo*-Ethenotetrahydrooripavine Series and Derived Analogs of N-Allylnormorphine and -norcodeine

K. W. Bentley and D. G. Hardy

Contribution from the Research Laboratories, Reckitt and Sons Ltd., Kingston-upon-Hull, England. Received September 26, 1966

**Abstract:** Secondary and tertiary alcohols of general structures IV and V have been prepared by the demethylation of the corresponding bases I and II described in part II of this series. The phenols so obtained are analgesics of extremely high potency, up to an unprecedented 12,000 times that of morphine. The bases of this and earlier series have been converted into analogs of N-allylnormorphine and N-allylnorcodeine of general structures XI and XII via the N-cyanonor compounds and via novel N,N'-methylenebis compounds XIII resulting from the reaction of the bases I and II with methyl azodicarboxylate. Some bases of the series XII are morphine antagonists of unprecedented potency, up to 150 times that of N-allylnormorphine.

In the preceding paper the preparation of two series of codeine derivatives of general structures I and II is reported, many of the members of which were considerably more active as analgesics than any base previously prepared in the morphine-thebaine group. Since the demethylation of codeine derivatives to the corresponding derivatives of morphine almost always results in an appreciable increase in analgesic activity, most of the alcohols of structures I and II were converted into the related phenols. The O-demethylation cannot be accomplished without decomposition by typical reagents owing to the extreme ease with which the alcohols undergo acid-catalyzed rearrangement,<sup>1c</sup> which was effected in most cases by heating the bases with potassium hydroxide in diethylene glycol at 200–220°. Methylation of the methyl ethers to the phenols to a very small extent was occasionally observed during the rearrangement reactions leading to the alcohols of structure I. The demethylating action of Grignard reagents is well known,<sup>2</sup> but the method has little preparative value.

The alkaline demethylations affected only the methyl group attached to C-3, that at C-6 remaining undisturbed. From the point of view of analgesic activity, however, the retention of the C-6 methoxyl group is advantageous, since methylation of the hydroxyl group at this position in morphine and codeine enhances the activity. The demethylation of the C-3 methoxyl group in the codeine-thebaine group under alkaline conditions appears to have been first observed during the Huang-Minlon reduction of thebenone.<sup>3</sup> The 4,5-oxygen bridge in these bases, which is unaffected under the conditions of the demethylation, also resembles the ether of a phenolic hydroxyl group, but none of this bridge during simple demethylations in the morphine series has never been observed, though

fused potassium hydroxide converts methylmorphenol into 3,4,5-trihydroxyphenanthrene.<sup>4</sup>

The bases obtained in this way, having structures III and IV, are listed in Tables I and II, respectively. In all cases it is found that demethylation of the C-3 methoxyl group results in an increase in analgesic potency, but the increase is by no means uniform throughout the series. The most potent compounds in this series do not correspond to the most potent of the methyl ethers, but, in a simple screening procedure in which analgesia is determined at a fixed time after administration of the compounds, comparisons are not always meaningful, since no account is taken of speed of onset, time of peak action, or duration of analgesia. The most potent analgesics in the morphine series reported prior to this work are about 12 times as active as morphine, but in other groups higher activities than this have frequently been encountered. The highest well-documented activities are reported in a series of benzimidazoles, of which the most active is about 1000 times as potent as morphine.<sup>5</sup> Of the oripavine

derivatives listed in Tables I and II, many are more active than any of the benzimidazoles, and in particular the alcohol IV (R = Me, R' = *n*-Pr), which is about 12,000 times as active as morphine, is the most potent analgesic so far reported. The very high potency of the phenols of structures III and IV makes them eminently suitable for use in large animals and the base III (R = Me, R' = *n*-Pr) is already widely used for the immobilization of wild animals for game conservation and veterinary purposes.<sup>6,7</sup>

Several of the bases of the tetrahydrooripavine series III and IV have proved to be inaccessible. Bases of either of these structures in which one of the groups R or R' contains the system CHC=C or CH—aryl directly attached to the hydroxyl-bearing carbon atom fail to survive the vigorous conditions necessary for the alkaline demethylation process, owing to the ease with which they suffer base-catalyzed dehydration to polymerizable derivatives.

(7) A. M. Harthoorn and J. Bligh, *Res. Vet. Sci.*, **6**, 290 (1965); A. M. Harthoorn, *J. S. African Vet. Med. Assoc.*, **36**, 45 (1965).

Esterification of the phenolic hydroxyl group of the tetrahydrooripavine derivatives is very easily accomplished by the conventional methods and, in general, results in some reduction in analgesic activity, though the 3-O-acetyl derivative of the base III (R = Me, R' = *n*-Pr) is more than twice as active as the parent phenol. The esters are very readily hydrolyzed even on heating aqueous solutions of their salts. The esters prepared are listed in Table III.

### Derivatives of Nor Bases

It has been shown that N-allylnormorphine<sup>8</sup> (nalorphine) (V, R = CH<sub>2</sub>CH=CH<sub>2</sub>) antagonizes the action of morphine (V, R = Me) in animals and in man,<sup>9</sup> and that its administration to narcotics addicts precipitates withdrawal symptoms. Physical dependence on the drug does not appear to develop after prolonged administration, and it is widely believed to be non-addicting.<sup>10</sup> Although the compound does not show

up as an analgesic when tested by the conventional techniques in laboratory animals, it has been shown to be an analgesic effective against natural pain in man, and to have a potency in such conditions about equal to that of morphine itself.<sup>11</sup> It has been very widely studied in clinical investigations, but has been found to produce bizarre and often distressing mental effects in a number of patients, with the result that it has found little clinical use as an analgesic.

The series of alcohols of general structures III and IV, and their 3-O-methyl ethers described in the previous paper, having a very wide range of morphine-like activity, provide a large number of starting materials, and many of these have been converted into analogs of nalorphine. Normorphine (V, R = H), from which other tertiary bases in the morphine series are prepared, is obtained from diacetylmorphine by treatment with cyanogen bromide and hydrolysis of the resulting N-cyanonor compound with dilute hydrochloric acid.<sup>8</sup> Cyanogen bromide reacts with the ketone VI (R = Me) and its analogs, the phenols of general structures III and IV, and their methyl ethers to give the corresponding N-cyanonor compounds in very good yield. Since the rate of quaternization of all of the bases in this series is very low, quaternary salt formation with liberated methyl bromide is not a complicating factor in the reaction.

The alcohols of general structures VII and VIII and the corresponding 6,14-ethano compounds, being very readily rearranged by acids, can only be hydrolyzed at the N-cyano group under alkaline conditions, most conveniently by heating with potassium hydroxide in diethylene glycol at 160° for 5–10 min, or at 200–220°

for longer periods if the simultaneous O-demethylation of VII to VIII is also required. The ketones of structure VI are, however, unstable to alkalis, and hydrolysis of the N-cyano group of the cyanamide VI (R = CN) must be effected with dilute mineral acid, to which the ring structure is stable. The hydrolysis is, however, incomplete, and the principal product is the substituted urea VI (R = CONH<sub>2</sub>). The required secondary base VI (R = H) is, however, preparable by the action of nitrous acid on the urea in 50% yield.

The preferred method of preparation of the ketonic secondary base VI (R = H) is the reaction of the tertiary base VI (R = Me) with methyl azodicarboxylate. The initial product of this reaction, which is presumably the substituted hydrazo ester VI (R = CH<sub>2</sub>N(COOMe)—NHCOOMe), is very readily hydrolyzed by cold aqueous 1 N hydrochloric acid, with the separation of the sparingly soluble hydrochloride of the secondary base VI (R = H) and the liberation of formaldehyde and methyl hydrazodicarboxylate. Norcodeine has been prepared by this general process, but the yield is poor.<sup>12,13</sup> The application of this reaction to the alcohols of general structure VII (R<sup>2</sup> = Me) and their 6,14-ethano analogs does not lead directly to the production of the corresponding secondary bases VII (R<sup>2</sup> = H). These alcohols react readily with methyl or ethyl azodicarboxylate in acetone solution, but the hydrolysis of the primary reaction products with mineral acid in the cold affords solutions from which no salt separates. The basification of these solutions affords products that initially are very soluble in methanol, but are rapidly converted in hot methanol into sparingly soluble, high-melting bases. Similar results are obtained, though more slowly, when the primary reaction products are hydrolyzed with aqueous methanol instead of acid.

The final high-melting products are not carbinolamines VII (R<sup>2</sup> = CH<sub>2</sub>OH), as these are lower melting, more soluble bases preparable by the action of formaldehyde on the secondary bases, but they are obtained from the carbinolamines by heating these alone, or better with secondary base, in solution. Whereas on heating with an aqueous acid solution of 2,4-dinitrophenylhydrazine, the carbinolamines give 1 molecular equiv of formaldehyde dinitrophenylhydrazone, the high-melting products under similar conditions afford only 0.5 equiv of the hydrazone. It is clear from these facts that the high-melting bases are N,N'-methylenebis-nor bases of general structure IX, and nmr spectral studies support this conclusion. The spectra of the base VII (R = R<sup>1</sup> = R<sup>2</sup> = Me) and the bis compound IX (R = R<sup>1</sup> = R<sup>2</sup> = R<sup>3</sup> = Me) are identical in all important respects apart from the absence from the spectrum of the latter base of the characteristic signal due to NCH<sub>3</sub>.

Unsymmetrical bis compounds of structure IX can be prepared by the interaction of carbinolamines VII (R<sup>2</sup> = CH<sub>2</sub>OH) and secondary bases VII (R<sup>2</sup> = H) differing in the nature of the HOCRR<sup>1</sup> substituent at C-7; for example, the same unsymmetrical base is obtained by heating the carbinolamine VII (R = R<sup>1</sup> = Me, R<sup>2</sup> = CH<sub>2</sub>OH) with the secondary base VII (R = Me, R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph, R<sup>2</sup> = H) or the carbinolamine VII

(R = Me, R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph, R<sup>2</sup> = CH<sub>2</sub>OH) with the secondary base VII (R = R<sup>1</sup> = Me, R<sup>2</sup> = H). The symmetrical bis compounds IX (R = R<sup>2</sup>, R<sup>1</sup> = R<sup>3</sup>) presumably arise in this way after hydrolysis of the substituted hydrazo ester as follows.

In the hydrolysis of the hydrazo ester derived from the ketone VI (R = Me) the secondary base VI (R = H) is obtained rather than the bis compound as a result of the low solubility of its hydrochloride. The bis compounds are soluble in aqueous acids in which they are converted into carbinolamines and secondary bases which revert to the bis compounds on standing or heating in solution. When the compounds are heated in solution in dilute acetic acid, formaldehyde is slowly lost, and the secondary bases may be recovered from the solution; mineral acid solutions cannot be used for this purpose owing to the ease with which the alcohols of these series are rearranged in warm solutions of strong acids. The bis compounds of general structure IX prepared by these processes are listed in Table IV.

The secondary base VI (R = H) has been converted into a series of analogs of nalorphine V (R = CH<sub>2</sub>CH=CH<sub>2</sub>) by treatment with alkyl, alkenyl, or alkynyl halides RX under reflux in inert solvents. Quaternary salt formation with the 6,14-etheno and ethano tetrahydrothebaine derivatives is so slow that

excellent yields of tertiary bases may be obtained without difficulty. A list of ketones of general structure VI and corresponding 6,14-ethano compounds is given in Table V.

Nonphenolic and phenolic alcohols of general structures VII and VIII in which R<sup>2</sup> is other than methyl or hydrogen, which also are analogs of nalorphine, have been prepared by one or other of the following general processes.

(a) Conversion of the appropriate N-substituted nor ketone VI, in which R has the desired value, into alcohols by reduction with sodium borohydride or aluminum isopropoxide, or treatment with the appropriate Grignard reagent or lithium alkyl: in general, this process leads to mixtures of alcohols containing, in many cases, appreciable quantities of the product of Grignard reduction (see preceding paper), and the separation of pure products is frequently tedious. It does not give phenols directly.

(b) Alkylation, alkenylation, or alkynylation of the appropriate secondary bases VII (R<sup>2</sup> = H) and VIII, (R<sup>2</sup> = H) may be achieved by heating under reflux with the desired halide R<sup>2</sup>X or alternatively by acylation with an acyl halide R<sup>2</sup>COCl, followed by reduction of the resulting amide with lithium aluminum hydride. These processes readily afford pure isomers of the alcohols, since the separation of pure starting materials VII (R<sup>2</sup> = Me) and VIII (R<sup>2</sup> = Me) may be accomplished relatively easily before N-demethylation to secondary base. Phenolic bases are readily obtained in this way.

(c) Tertiary bases are obtained by heating the *N,N'*-methylenebisnor compounds of general structure IX (R = R<sup>2</sup>, R<sup>1</sup> = R<sup>3</sup>) with the appropriate halide and, since the bis compounds are prepared from pure al-

is of the N-methyl series, this process also affords chemically pure products. However, this process is generally less satisfactory than the alkylation of the tertiary bases since only the most reactive halides react readily with the bis compounds; in other cases prolonged periods of heating with the halide is necessary and some quaternization of the resulting tertiary bases takes place under these conditions. Alternatively, tertiary bases are obtainable from the bis compounds by action of these with acyl halides, which proceeds easily, followed by reduction of the resulting amides with lithium aluminum hydride. Neither of these alternatives yields phenols directly since the phenolic compounds are not accessible by the action of methyl isocarbonylate on the phenolic N-methyl bases VIII ( $R = \text{Me}$ ).

Enolic bases of general structure VIII, when not prepared directly as in b above, may be obtained by the methylation of the corresponding base VII as previously described in the case of the N-methyl compounds.

Bases corresponding to those of series VII and VIII containing a 6,14-ethano instead of an etheno bridge can be prepared by analogous processes to those set forth above, starting from the corresponding 6,14-ethanol or alcohols.

Bases prepared by these methods are listed in Tables X. The pharmacological testing of the compounds listed in Tables V–IX presents certain difficulties since nalorphine-like substances are not revealed by the conventional screening techniques in experimental animals, and the results of pharmacological studies are being and will be reported in detail elsewhere.<sup>14</sup> It may, however, be stated here that the structure-activity relationships in the various series are complex, and that the physiological activity of each base is dependent on the nature of the substituents on the nitrogen atom, the C-3 oxygen atom, and in the alkoxy group. No group has been found that, when substituted for methyl attached to the nitrogen atom, reverses morphine-antagonist properties on all of the bases, and each of the series represented in Tables VI–IX contains potent morphine-like analgesics, as well as morphine antagonists and also several bases resembling morphine in some and nalorphine in other respects. For example, the base VIII ( $R = \text{Me}$ ,  $R^1 = n\text{-Pr}$ ,  $R^2 = \text{CH}_2\text{CH}=\text{CMe}_2$ ) is a potent morphine-like agent, while base VIII ( $R = R^1 = \text{Me}$ ,  $R^2 = \text{CH}_2\text{C}_3\text{H}_5$ , 6,14-ethano) is the most potent morphine antagonist so far tested, being some 150 times more potent than morphine. The base VIII ( $R = \text{Me}$ ,  $R^1 = i\text{-Am}$ ,  $R^2 = \text{CH}_2\text{C}_3\text{H}_5$ ), however, shows morphine-like analgesic properties which are reversed by nalorphine only if the antagonist is given very soon after the drug, but, like nalorphine, it causes an increase in urinary output (morphine causes a decrease) and a decrease in locomotor activity in mice (morphine causes an increase). The physiological activity of the last mentioned base was tested in animals for up to 3 days.

Some information concerning certain of the bases of this group has already been published: D. Campbell, R. E. Lister, and G. W. Bentley, *Clin. Pharmacol. Therap.*, **5**, 193 (1964); R. E. Lister, J. Bentley, and G. W. Bentley, *Pharmacol.*, **16**, 364 (1964); K. W. Bentley, A. L. Boura, A. E. Hardy, D. G. Hardy, A. McCoubrey, M. L. Aikman, and R. E. Bentley, *Nature*, **206**, 102 (1965); A. L. A. Boura and A. E. Fitzgerald, *Pharmacol.*, **26**, 307 (1966).

Even the secondary bases in the series have been found to be unusual. Many of them are morphine-like analgesics, and this is without precedent in the morphine, morphinan, benzomorphan, and pethidine series; indeed secondary bases in general are inactive in the conventional tests.

The unprecedented potency of some members of the series I, II, III, and IV requires some comment. The bases would not be expected to be more acceptable than morphine at the receptor surface depicted by Beckett<sup>15</sup> since the added portions of the molecule would be expected to project outside the limited area of such a surface. Two alternative explanations of the high activities are possible. Either the receptor surface is more extensive than that depicted by Beckett and has additional points of possible attachment by which the more extensive molecules of the bases I–IV, but not morphine or simpler bases, can be bound, or the molecules are no more acceptable than morphine at the receptor but arrive there in vastly greater numbers as a result of selective concentration in the tissues of the central nervous system. There is some evidence from preliminary distribution studies using labeled material that relatively high concentrations of the base III ( $R = \text{Me}$ ,  $R^1 = n\text{-Pr}$ ) are found in the brain about 0.5 hr after intramuscular or subcutaneous injection, but this alone cannot account for the very high potency of the base, and the problem clearly requires further study.

## Experimental Section

The O-demethylation of the alcohols of general structures I and II were effected by the following general method.

**7 $\alpha$ -(1-Hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydrooripavine (III,  $R = R^1 = \text{Me}$ ).** 7 $\alpha$ -(1-Hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydrothebaine (I,  $R = R^1 = \text{Me}$ ) (8 g) was added to a solution of potassium hydroxide (60 g) in diethylene glycol (150 ml) boiling under reflux at 200–210°. The mixture was boiled and stirred vigorously under reflux until a test portion on dilution with ten times its volume of water gave a homogeneous solution. The mixture was then diluted with five times its volume of water and a solution of ammonium chloride was added until precipitation of the phenol ceased. The product was isolated by ether extraction and recrystallized from aqueous 2-ethoxyethanol with charcoal treatment, when the oripavine derivative was obtained as elongated plates, mp 266° (4.2 g).

*Anal.* Calcd for  $\text{C}_{22}\text{H}_{28}\text{NO}_4$ : C, 72.1; H, 7.6. Found: C, 72.4; H, 7.5.

The 3-O-acetyl ester was precipitated on the addition of acetic anhydride to a solution of the phenol in aqueous sodium hydroxide and was obtained as white prisms, mp 191°, from ethanol.

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{30}\text{NO}_5$ : C, 70.5; H, 7.3. Found: C, 70.5; H, 7.2.

**7 $\alpha$ -(1-(*R*)-Hydroxy-1-methylbutyl)-6,14-endo-ethenotetrahydrooripavine (III,  $R = \text{Me}$ ;  $R^1 = n\text{-Pr}$ ).** 7 $\alpha$ -(1-(*R*)-Hydroxy-1-methylbutyl)-6,14-endo-ethenotetrahydrothebaine (I,  $R = \text{Me}$ ;  $R^1 = n\text{-Pr}$ ) (50 g) was demethylated with potassium hydroxide (360 g) and diethylene glycol (950 ml) at 205–215° until a test portion of the reaction mixture on dilution with ten times its volume of water gave a homogeneous solution. The mixture was diluted with water (4500 ml), and the solution was filtered through charcoal and aqueous ammonium chloride was added until precipitation of the phenol ceased. The solid (32 g) was collected, washed well with water, and recrystallized from aqueous 2-ethoxyethanol, when it was obtained as off-white prisms, mp 215–216°.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{32}\text{NO}_4 \cdot \text{H}_2\text{O}$ : C, 70.0; H, 8.1. Found: C, 70.0; H, 7.9.

The 3-O-acetyl ester was prepared by heating the phenol under reflux with acetic anhydride and anhydrous sodium acetate and was obtained as off-white prisms, mp 196°, from ethanol.

*Anal.* Calcd for  $\text{C}_{25}\text{H}_{34}\text{NO}_5$ : C, 71.5; H, 7.7. Found: C, 71.3; H, 7.7.

\* For bases where R<sup>2</sup> = Me, see Table I, ref 1a. <sup>†</sup> Bitartrate.

The 3-O-propionyl ester was obtained (from the phenol, propionic anhydride, and sodium propionate) as off-white prisms, mp 130°, from aqueous ethanol.

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>4</sub>: C, 71.9; H, 7.9. Found: C, 71.8; H, 7.9.

N-Cyano-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = CN). 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = Me) (50 g) was heated under reflux with cyanogen bromide (16 g) in dry alcohol-free chloroform (350 ml) for 12 hr. The chloroform was evaporated, and the residue was recrystallized from 2-ethoxyethanol, when the N-cyanonor compound (48 g) was obtained as colorless prisms, mp 236°,  $\nu_{\max}$  2250 and 1715 cm<sup>-1</sup>.

Anal. Calcd for C<sub>23</sub>H<sub>27</sub>N<sub>2</sub>O<sub>4</sub>: C, 70.4; H, 6.2. Found: C, 70.2; H, 6.4.

N-Aminocarbonyl-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = CONH<sub>2</sub>). N-Cyano-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = CN) (40 g), finely powdered, was boiled under reflux with 2 N hydrochloric acid (400 ml), in the presence of a small amount of a neutral wetting agent to minimize frothing, until all the solid had dissolved (~2 hr). The solution was cooled, and a small portion was neutralized with ammonia, when a viscous gum was obtained, from which the crystalline N-aminocarbonyl compound was obtained with difficulty on crystallization from methanol as prisms, mp 220°.

Anal. Calcd for C<sub>23</sub>H<sub>29</sub>N<sub>2</sub>O<sub>5</sub>: C, 67.3; H, 6.4; N, 6.8. Found: C, 67.1; H, 6.4; N, 6.8.

7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = H). a. The acid solution obtained by the hydrolysis of N-cyano-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = CN) (40 g) as above was cooled to 0°, and an aqueous solution of sodium nitrite (8 g) was slowly added with vigorous stirring. When evolution of gas ceased, the mixture was made alkaline with ammonia and extracted with chloroform. Evaporation of the extract gave a viscous gum, which was converted into the crystalline hydrochloride with methanolic hydrogen chloride. The salt (25 g) was obtained as plates, mp 350°, from hot water.

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>4</sub>·HCl·0.5H<sub>2</sub>O: C, 64.0; H, 6.6. Found: C, 63.9; H, 6.3.

The base recovered from the hydrochloride was obtained as needles, mp 73°, from water.

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>4</sub>·H<sub>2</sub>O: C, 68.8; H, 7.0. Found: 68.8; H, 7.2.

The picrate was obtained as yellow prisms, mp 273°, from ethanol.

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>N<sub>2</sub>O<sub>11</sub>: C, 56.4; H, 4.7; N, 9.4. Found: C, 56.0; H, 4.7; N, 9.4.

The N-acetyl compound was prepared by heating the base with acetic anhydride and was obtained as prisms, mp 101°, from aqueous methanol.

Anal. Calcd for C<sub>25</sub>H<sub>27</sub>NO<sub>5</sub>·H<sub>2</sub>O: C, 67.4; H, 6.8. Found: C, 67.3; H, 6.8.

The N-cyclopropylcarbonyl compound, from the base and cyclopropylcarbonyl chloride and anhydrous potassium carbonate in ether, was obtained as prisms, mp 197°.

Anal. Calcd for C<sub>26</sub>H<sub>29</sub>NO<sub>4</sub>: C, 71.7; H, 6.7. Found: C, 71.8; H, 6.8.

b. A solution of 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (10 g) (VI, R = Me) and methyl azodicarboxylate (3.84 g) in acetone (75 ml) was evaporated to dryness over about 30 min. The viscous yellow residue was dissolved in 1 N hydrochloric acid (40 ml) with vigorous stirring and the solution set aside until separation of solid

matter ceased (~1 hr). The hydrate was washed with ice water, and a water when the nor base (X, R = 1) as prisms, mp 350°, identical in infrared with material prepared as in part a.

N-Allyl-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydronorthebaine (VI, R = CH<sub>2</sub>CH=CH<sub>2</sub>). 7 $\alpha$ -Acetylthebaine (VI, R = H) (20 g), all sodium carbonate (10 g), and ethanol under reflux for 18 hr. The mixture leaving the base as an uncrystallizable hydrochloride (22 g) as plates, mp 2 hydrogen chloride.

Anal. Calcd for C<sub>25</sub>H<sub>29</sub>NO<sub>4</sub>·HCl: Found: C, 64.8; H, 7.1.

Other N-substituted nor bases of the secondary base VI and are listed in Table V.

N-Cyano-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VII, R = R<sup>1</sup> = 1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VII, R = R<sup>1</sup> = Me) (15 g), cyanogen bromide (50 ml) were heated under reflux for 24 hr. The solution was evaporated, and the residue was finely powdered and extracted with hydrochloric acid, then collected, recrystallized from aqueous 2-ethoxyethanol compound (14.8 g) was obtained, mp 2250 cm<sup>-1</sup>.

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>N<sub>2</sub>O<sub>4</sub>: Found: C, 70.7; H, 7.1.

N-Cyano-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VIII, R = R<sup>1</sup> = cyanogen bromide (5.3 g), 7 $\alpha$ -endo-ethenotetrahydronorthebaine (V, g) in dry methylene chloride was The product (14.8 g) isolated by acid washing of the powdered residue mp 275°, from aqueous 2-ethoxyethanol.

Anal. Calcd for C<sub>25</sub>H<sub>29</sub>N<sub>2</sub>O<sub>4</sub>: Found: C, 70.1; H, 6.4.

7 $\alpha$ -(1-Hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = CN) (57 g) was solution of potassium hydroxide (1 ml) at 165–170°, and the mixture until evolution of ammonia ceased was then poured into vigorously stirred crushed ice, and the precipitated solid was washed with water, when the secondary prisms, mp 163°. (A low-melting solid was obtained in initial experiments, and a ca. 0.5 solution by rapid cooling.)

Anal. Calcd for C<sub>26</sub>H<sub>29</sub>NO<sub>4</sub>: Found: C, 72.3; H, 7.8.

The hydrolysis of other N-cyano secondary bases was effected in the same manner as that did not crystallize on dilution with water were isolated by ether extraction with organic solvents of the residue

dilution with ten times its volume of water gave a homogeneous solution (~30–40 min). The mixture was rapidly cooled and poured with vigorous stirring into ice-water (2500 ml), and the phenol was then precipitated by the addition of saturated aqueous ammonium chloride. The product (80 g), mp 280–282°, was collected, washed well with water, and recrystallized from methanol, when the phenolic base XII (R = R<sup>1</sup> = Me, R<sup>2</sup> = H) was obtained as prisms, mp 284°.

Anal. Calcd for C<sub>22</sub>H<sub>27</sub>NO<sub>4</sub>: C, 71.5; H, 7.3. Found: C, 71.3; H, 7.4.

b. N-Cyano-7α-(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronororpavine (VIII, R = R<sup>1</sup> = Me; R<sup>2</sup> = CN) (5 g) was hydrolyzed with potassium hydroxide (5 g) and diethylene glycol (40 ml) at 160–170° for 10 min. The mixture was poured into water (250 ml) and the phenol was precipitated with ammonium chloride, collected, washed, and recrystallized from aqueous 2-ethoxyethanol, when it was obtained (3.1 g) as prisms, mp 284°, identical in infrared absorption, mixture melting point, and R<sub>f</sub> value with material obtained as in part a above.

c. 19-Methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (2 g) was O-demethylated by heating with potassium hydroxide

(2.5 g) and diethylene glycol (12.5 ml) at 210° until a test portion gave a homogeneous solution on dilution with water. The mixture was then diluted with water (65 ml), and the product was precipitated with ammonium chloride, when 19-methylnororvinol (VIII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (0.8 g) was obtained as prisms, mp 284°, from 2-ethoxyethanol, identical with the base obtained in a and b above.

Other phenolic secondary bases of structure VIII, (R<sup>2</sup> = H) were prepared by the combined hydrolysis and O-demethylation of N-cyano compounds of the tetrahydrothebaine series VII, (R<sup>2</sup> = CN) by the process given in part a above.

N-Allyl-7α-(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = CH<sub>2</sub>CH=CH<sub>2</sub>) (N-Allyl-19-methylnorthevinol). a. 19-Methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (3.4 g), allyl bromide (1 g), anhydrous sodium carbonate (2 g), and ethanol (40 ml) were boiled together under reflux for 18 hr. The mixture was filtered and evaporated, leaving a viscous gum that crystallized on standing. It was recrystallized from petroleum ether (bp 40–60°), when N-allyl-19-methylnororvinol was obtained (3.0 g) as white prisms, mp 104°.

Anal. Calcd for C<sub>28</sub>H<sub>33</sub>NO<sub>4</sub>: C, 73.7; H, 7.9. Found: C, 74.0; H, 8.0.

b. N-Allyl-7α-acetyl-6,14-endo-ethenotetrahydrothebaine (N-Allylnorthevinone, VI, R = CH<sub>2</sub>CH=CH<sub>2</sub>) (10 g) in ether (350 ml) was slowly added to a vigorously stirred solution of methylmagnesium iodide (from 1.67 g of magnesium and 9.9 g of methyl iodide) in ether (200 ml). The mixture was stirred and heated under reflux for 2 hr and poured into aqueous ammonium chloride. The ether layer was separated, dried, and evaporated, leaving a residue that crystallized on standing. Recrystallization of the product from petroleum ether (bp 40–60°) afforded N-allyl-19-methylnorthevinol (8.9 g) as white prisms, mp 104°, identical in infrared absorption, mixture melting point, and R<sub>f</sub> value with the base prepared as in part a above.

The base was also obtained from *N,N'*-methylenebis(19-ynorthevinol) (IX,  $R = R^1 = R^2 = R^3 = \text{Me}$ ) and allyl iodide (see below).

her *N*-substituted nor bases of the general formula VII were prepared from the corresponding secondary bases by heating the appropriate alkyl, alkenyl, or alkynyl halide, sodium iodide, and a solvent, generally ethanol, though acetone or ethyl ketone was the preferred solvent for 3,3-dimethylbromide since solvolysis of the halide appeared to occur when iodide was used.

**N-Allyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydropavine (VIII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{CH}_2\text{CH}=\text{CH}_2$ ) (19-methylnororvinol).** a. 7 $\alpha$ -(1-Hydroxy-1-methylethyl)-endo-ethenotetrahydronororipavine (VIII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{H}$ ) (19-methylnororvinol) (3.4 g), allyl bromide (1 g), anhydrous sodium carbonate (2 g), and ethanol (80 ml) were boiled under reflux for 18 hr. The mixture was filtered and washed, and the residue was recrystallized from methanol, when *N*-allyl compound (3.0 g) was obtained as white prisms, mp on slow heating, 210° on plunging into a bath heated above

al. Calcd for  $\text{C}_{25}\text{H}_{31}\text{NO}_4$ : C, 73.3; H, 7.6. Found: C, 73.4; H, 7.4.

**N-Allyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (N-allyl-19-methylnorthevinol, VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{CH}_2\text{CH}=\text{CH}_2$ ) (2 g)** was demethylated by heating with potassium hydroxide (2.5 g) and diethylene glycol (ml) at 200–210° until a homogeneous solution was obtained on addition of a test portion with ten times its volume of water. The mixture was then poured into aqueous ammonium chloride, and the solid was isolated by ether extraction, when it was obtained, after recrystallization from methanol, as white prisms (0.8 g), mp 120–121°, identical with material prepared as in part a above.

her *N*-substituted nor bases of the phenolic series VIII were prepared as in a by the action of alkyl, alkenyl, or alkynyl halides on the appropriate secondary base VIII ( $R^2 = \text{H}$ ), though with methylallyl bromide acetone was used as the solvent.

**Cyclopropylcarbonyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-tetrahydronorthebaine (N-Cyclopropylcarbonyl-19-methylnororvinol, VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{cyclopropylcarbonyl}$ ).** Secondary base 19-methylnorthevinol (VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{H}$ ) (5 g) was stirred in dry ether (150 ml) with anhydrous potassium carbonate (5 g) and cyclopropyl carbonyl chloride (1.4 g) for 5 hr. Water and dilute hydrochloric acid were then added, and the ether layer was separated, washed with water, dried, and evaporated, leaving the nonbasic amide as prisms, mp 212° (3.5 g) to 214°,  $\nu_{\text{max}}$  1640  $\text{cm}^{-1}$ , on recrystallization from methanol.

al. Calcd for  $\text{C}_{27}\text{H}_{33}\text{NO}_5$ : C, 71.7; H, 7.3. Found: C, 71.8; H, 7.3.

**N-Cyclopropylmethyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-tetrahydronorthebaine (N-Cyclopropylmethyl-19-methylnororvinol, VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{cyclopropylmethyl}$ ).** The amide cyclopropylcarbonyl-19-methylnororvinol (VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{H}$ ) (5 g) was stirred in dry ether (150 ml) with anhydrous lithium aluminum hydride for 5 hr. The excess of hydride was cautiously destroyed by addition of an aqueous solution of potassium sodium tartrate, the tetrahydrofuran layer was separated. The aqueous layer was extracted with ether, and the combined organic solutions were dried and evaporated, when the tertiary base was obtained as a gum, which slowly crystallized. Recrystallization of the product from methanol afforded 1.4 g of colorless prisms, mp 124°.

al. Calcd for  $\text{C}_{27}\text{H}_{33}\text{NO}_4$ : C, 74.2; H, 8.0. Found: C, 74.3; H, 7.8.

base with ethanolic hydrogen chloride and adding dry ether. The solid was obtained as white prisms, mp 266°.

al. Calcd for  $\text{C}_{27}\text{H}_{33}\text{NO}_4 \cdot \text{HCl}$ : C, 68.4; H, 7.6. Found: C, 68.5; H, 7.8.

ter tertiary bases of general structure VII could be prepared by the amide and reduction with lithium aluminum hydride in a manner similar to the above.

**Cyclopropylcarbonyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-tetrahydronororipavine (N-Cyclopropylcarbonyl-19-methylnororvinol, VIII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{cyclopropylcarbonyl}$ ).** The phenolic secondary base 19-methylnororvinol (VIII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{H}$ ) (5 g) was stirred in dry ether (150 ml) with anhydrous sodium carbonate (5 g) and cyclopropylcarbonyl chloride (2.4 g) for 6 hr. The solution was stirred with 1 *N* hydrochloric acid (ml) for 5 min, the ether layer was separated, washed, dried,

and evaporated, leaving the amide as a solid residue. This was recrystallized from ethanol, when it was obtained as white prisms, mp 290°, giving a blue color with ferric chloride and instantly soluble when an ethanolic solution was added to an excess of cold aqueous sodium hydroxide.

Anal. Calcd for  $\text{C}_{28}\text{H}_{31}\text{NO}_5$ : C, 71.4; H, 7.1. Found: C, 71.5; H, 7.3.

**N-Cyclopropylmethyl-7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine (N-Cyclopropylmethyl-19-methylnororvinol, VIII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{cyclopropylmethyl}$ ).** The amide VIII ( $R = R^1 = \text{Me}$ ;  $R^2 = \text{cyclopropylcarbonyl}$ ) (4 g) was reduced with lithium aluminum hydride (2.15 g) in tetrahydrofuran under reflux over 5 hr. The product was isolated by the cautious addition of an aqueous solution of potassium sodium tartrate and ether extraction, when the tertiary base was obtained as white prisms, mp 234°, on recrystallization from methanol.

Anal. Calcd for  $\text{C}_{28}\text{H}_{31}\text{NO}_4$ : C, 73.6; H, 7.8. Found: C, 73.6; H, 7.9.

Other *N*-substituted bases of the phenolic series VIII were prepared *via* the amide and reduction with lithium aluminum hydride by the same method described above.

**N,N'-Methylenebis(7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine) (N,N'-Methylenebis(19-methylnororvinol), IX,  $R = R^1 = R^2 = R^3 = \text{Me}$ ).** a. A solution of 19-methylnororvinol (I,  $R = R^1 = \text{Me}$ ) (10 g) and methyl azodicarboxylate (3.64 g) in acetone (75 ml) was evaporated to dryness over 30 min. The viscous yellow product was dissolved in cold 1 *N* hydrochloric acid (100 ml) and the solution kept at room temperature for 45 min. The base was precipitated with ammonia and rapidly extracted with ether. The undried extract was evaporated, the viscous residue dissolved in methanol (50 ml), and the solution heated to boiling. A white solid (8.4 g) rapidly separated and was collected and recrystallized from 2-ethoxyethanol, when the *N,N'*-methylenebis compound was obtained as white prisms, mp 286°.

Anal. Calcd for  $\text{C}_{67}\text{H}_{86}\text{N}_2\text{O}_8$ : C, 72.5; H, 7.4. Found: C, 72.3; H, 7.5.

b. Aqueous formaldehyde (30%, 1 ml) was added to a solution of 19-methylnororvinol (VII,  $R = R^1 = \text{Me}$ ;  $R^2 = \text{H}$ ) (2 g) in ethanol (15 ml). The mixture was kept at the room temperature for 45 min, diluted with water, and extracted with ether. The ether extract on evaporation yielded a viscous gum (2.01 g), 1 g of which on heating under reflux in methanol (5 ml) gave 0.85 g of the above *N,N'*-methylenebis compound (IX,  $R = R^1 = R^2 = R^3 = \text{Me}$ ). The remaining 1 g on heating with 19-methylnororvinol (1 g) in methanol (10 ml) afforded 1.8 g of the same *N,N'*-methylenebis compound, mp 286°.

**N-Hydroxymethyl-7 $\alpha$ -(1-(*R*)-hydroxy-1-methyl-3-phenylpropyl)-6,14-endo-ethenotetrahydronorthebaine (N-Hydroxymethyl-19-phenethylnorthevinol, VII,  $R = \text{Me}$ ;  $R^1 = \text{CH}_2\text{CH}_2\text{Ph}$ ;  $R^2 = \text{CH}_2\text{OH}$ ).** Aqueous formaldehyde (30%, 1 ml) was added to a warm solution of 19-phenethylnorthevinol (VII,  $R = \text{Me}$ ;  $R^1 = \text{CH}_2\text{CH}_2\text{Ph}$ ;  $R^2 = \text{H}$ ) (2 g) in ethanol (15 ml) and the mixture kept at 45° for 30 min during which time a crystalline solid separated. The mixture was cooled, and the solid (1.9 g) was collected and recrystallized from methanol containing 10% of aqueous 30% formaldehyde, when the carbinolamine (1.6 g) was obtained as white prisms, mp 123°.

Anal. Calcd for  $\text{C}_{21}\text{H}_{27}\text{NO}_5$ : C, 74.1; H, 7.4. Found: C, 74.6; H, 7.8.

**N,N'-Methylenebis(7 $\alpha$ -(1-(*R*)-hydroxy-1-methyl-3-phenylpropyl)-6,14-endo-ethenotetrahydronorthebaine) (N,N'-Methylenebis(19-phenethylnorthevinol), IX,  $R = R^1 = \text{Me}$ ;  $R^2 = R^3 = \text{CH}_2\text{CH}_2\text{Ph}$ ).**

a. A solution of 19-phenethylnorthevinol (60 g) and ethyl azodicarboxylate (24 g) in acetone (450 ml) was boiled under reflux for 1 hr. The acetone was then evaporated, and the residue was dissolved in methanol (600 ml) and water (75 ml) added. The solution was heated to boiling when a crystalline solid rapidly separated. The mixture was cooled, and the solid (42 g) was collected and a portion recrystallized from 1-propanol, when the *N,N'*-methylenebis compound was obtained as white prisms, mp 241–243°.

Anal. Calcd for  $\text{C}_{68}\text{H}_{86}\text{N}_2\text{O}_8$ : C, 76.4; H, 7.4; N, 2.9. Found: C, 76.4; H, 7.8; N, 2.9.

b. *N*-Hydroxymethyl-19-phenethylnorthevinol (VII,  $R = \text{Me}$ ;  $R^1 = \text{CH}_2\text{CH}_2\text{Ph}$ ;  $R^2 = \text{CH}_2\text{OH}$ ) (1 g) was heated in boiling ethanol (20 ml) until separation of crystalline material appeared to have ceased. The mixture was cooled and the solid (0.8 g) collected, when the *N,N'*-methylenebis compound was obtained as prisms, mp 238–240°, raised to 241–242° on recrystallization from 1-propanol.

c. N-Hydroxymethyl-19-phenethylnorthevinol (VII, R = Me; R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph; R<sup>2</sup> = CH<sub>2</sub>OH) (1 g) and 19-phenethylnorthevinol (VII, R = Me; R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph; R<sup>2</sup> = H) (0.93 g) were heated together in ethanol (25 ml) until separation of crystalline material appeared to have ceased. The mixture was cooled and the N,N'-methylenebis compound (1.7 g) was collected and recrystallized from 1-propanol, when it was obtained as white prisms, mp 241–243°.

N,N'-Methylene-7 $\alpha$ -(1-hydroxy-1-methylethyl)-7' $\alpha$ -(1-(R)-hydroxy-1-methyl-3-phenylpropyl)bis(6,14-endo-ethenotetrahydronorthebaine) (N,N'-Methylene-19-methyl-19'-phenethylbis(northevinol), IX, R = R<sup>1</sup> = R<sup>2</sup> = Me; R<sup>3</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph). a. N-Hydroxymethyl-19-phenethylnorthevinol (VII, R = Me; R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph; R<sup>2</sup> = CH<sub>2</sub>OH) (1 g) and 19-methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (0.76 g) were heated together in boiling ethanol until separation of the solid ceased. The mixture was cooled, and the product was collected (1.41 g) and recrystallized from 1-propanol, when it was obtained as white prisms, mp 218–220°.

Anal. Calcd for C<sub>34</sub>H<sub>44</sub>N<sub>2</sub>O<sub>2</sub>: C, 74.6; H, 7.7. Found: C, 74.3; H, 7.2.

b. Aqueous formaldehyde (30%, 1 ml) was added to a solution of 19-methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (1 g) in ethanol (10 ml), and after 30 min the solution was diluted with water (50 ml) and rapidly extracted with ether. The ether extract was evaporated at 20° *in vacuo*; the residue was dissolved in ethanol (20 ml) and heated with 19-phenethylnorthevinol (VII, R = Me, R<sup>1</sup> = CH<sub>2</sub>CH<sub>2</sub>Ph; R<sup>2</sup> = H) (1.24 g) until precipitation of solid ceased. The mixture was cooled and the above unsymmetrical bis compound (1.9 g) was collected and obtained as prisms, mp 218–220°, after recrystallization from 1-propanol.

Hydrolysis of N,N'-Methylenebis(7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydronorthebaine) (IX, R = R<sup>1</sup> = R<sup>2</sup> = R<sup>3</sup> = Me). a. The N,N'-methylenebis compound (500 g) was dissolved in 1 N hydrochloric acid (5 ml), and the solution was added to a solution of 2,4-dinitrophenylhydrazine (500 mg) in 3 N hydrochloric acid (10 ml). The mixture was warmed until separation of solid matter ceased. The solid was collected, washed with water, and dried (125 mg). On recrystallization from aqueous ethanol, it was obtained as orange needles, mp 165°, undepressed on mixing with formaldehyde 2,4-dinitrophenylhydrazone, mp 166°.

b. A solution of dimedone (0.2 g) in ethanol (5 ml) was added to a hot solution of the N,N'-methylenebis compounds (1 g) in 6% acetic acid. Methylene dimedone (0.19 g) was precipitated almost at once and was collected, when it was obtained as white prisms, mp 189° undepressed on mixing with an authentic specimen prepared from formaldehyde. The filtrate, after removal of this derivative, was basified with ammonia, and the precipitated base

was collected and recrystallized from aqueous methanol, when the secondary base (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = H) (0.8 g) was obtained as needles, mp 163°, identical with material prepared by the hydrolysis of the N-cyanonor compound (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = CN) as described above.

Reaction of N,N'-Methylenebis(7 $\alpha$ -(1-hydroxy-1-methylethyl)-6,14-endo-ethenotetrahydrothebaine) (IX, R = R<sup>1</sup> = R<sup>2</sup> = R<sup>3</sup> = Me) with Alkyl and Acyl Halides. a. The N,N'-methylenebis compound (1 g), methyl iodide (2 ml), anhydrous potassium carbonate (1 g), and ethanol (20 ml) were boiled together under reflux for 6 hr. Filtration and concentration of the solution afforded 19-methylthevinol (I, R = R' = Me) (1 g), mp 166° alone or mixed with an authentic specimen.

b. The bis compound (1 g), allyl bromide (2 ml), anhydrous potassium carbonate (1 g), and ethanol (20 ml) were boiled together under reflux for 16 hr. Filtration and evaporation of the solution yielded N-allyl-19-methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = CH<sub>2</sub>CH=CH<sub>2</sub>) (1 g), mp 104° on recrystallization from petroleum ether (bp 40–60°).

Other N-alkenylations and alkynylations of this and other methylenebis compounds using reactive halides such as propargyl bromide, allyl bromide, and dimethylallyl bromide were achieved under similar conditions. Less reactive alkyl halides, however, such as ethyl bromide, *n*-propyl iodide, etc., reacted less readily, and reflux periods of up to 3 days were necessary for complete reaction, and under such conditions quaternary salt formation was also observed.

c. The N,N'-methylenebis compound (1 g), anhydrous potassium carbonate (1 g), and cyclopropylcarbonyl chloride (0.5 g) were stirred together in dry ether (50 ml) for 6 hr. Water (10 ml) and 2 N hydrochloric acid (20 ml) were added, and the ether layer was separated and evaporated, when N-cyclopropylcarbonyl-19-methylnorthevinol (VII, R = R<sup>1</sup> = Me; R<sup>2</sup> = cyclopropylcarbonyl) (1.0 g) was obtained after recrystallization from methanol, mp 214°, undepressed on mixing with an authentic specimen prepared from the secondary base VII (R = R<sup>1</sup> = Me, R<sup>2</sup> = H).

# Novel Analgesics and Molecular Rearrangements in the Morphine-Thebaine Group. IV.<sup>1</sup> Acid-Catalyzed Rearrangements of Alcohols of the 6,14-*endo*-Ethenotetrahydrothebaine Series

K. W. Bentley, D. G. Hardy, and B. Meek

*Contribution from the Research Laboratories, Reckitt and Sons Ltd., Kingston-upon-Hull, England. Received September 26, 1966*

**Abstract:** Alcohols of general structure I have been dehydrated to olefins II which have been further converted into 14-alkenylcodeinones V, themselves transformed by further acid-catalyzed reactions into recycled products VII and IX and derivatives of 5,14-thebainone (XV). 14-(3-Methylbut-2-enyl)codeine (XXVII) has been converted into a derivative XXIX of (–)-sinomenilan, the structure of which has been demonstrated by spectral studies and by conversion *via* the bases XXX and XXXIII into the olefin XXXIV.

Alcohols of the 6,14-etheno- and -ethanotetrahydrothebaine and -oripavine groups described in preceding two papers in this series<sup>2</sup> are all unstable in media, in which they suffer dehydration and rearrangement, the speed, extent, and course of which depends on the nature of the alcoholic group and the bridge and on the conditions of the reaction. In these the first product appears to be an olefin. The alcohols are generally preparable in good yield by heating alcohols in 98–100% formic acid, though in some cases further reaction takes place before complete dehydration occurs. In no case was evidence obtained of production of more than one olefin, and in the cases examined the olefin is the product of dehydration of the side chain rather than toward C-7.

Olefin II ( $R^1 = R^2 = H$ ) on ozonolysis affords propionaldehyde and the ketone III, and the olefin II ( $R^1 = H, R^2 = Et$ ) yields propionaldehyde, thus confirming the structures assigned to these bases. The structure II ( $R^1 = R^2 = H$ ) for the olefin derived from the alcohol I ( $R = Me$ ) is further confirmed by its reaction from the ketone III by the Wittig reaction, by its nmr spectrum, which shows a two-proton signal at  $\delta$  4.80 ( $H_2C=C<$ ) and a three-proton signal at  $\delta$  6.60 ( $=CCH_3$ ). The production of the same olefin II ( $R^1 = H, R^2 = Me$ ) from two diastereoisomeric alcohols of structure I ( $R = Et$ ) and of the olefin II ( $R^1 = H, R^2 = Et$ ) from two alcohols of structure I ( $R = n\text{-Pr}$ ) shows that the alcohols in each case are diastereoisomers at the asymmetric alcoholic carbon and do not differ at C-7.<sup>2,3</sup>

Olefins analogous to those of structure II, but bearing a 6,14-ethano bridge are preparable by the dehydration of 6,14-ethano analogs of the alcohols of structure I. Catalytic reduction of the olefins II in general results in saturation of the 6,14-etheno bridge, which is sterically less hindered than in the alcohols I, but in contrast to the methylene group in the olefin II ( $R^1 =$

$R^2 = H$ ) is also reduced; the more heavily substituted double bond in the olefin II ( $R = H, R^1 = n\text{-Pr}$ ) is more resistant to reduction.

The olefins themselves are unstable under acid conditions, but the ease of rearrangement appears to depend on the degree of substitution of the double bond. For example, the olefin II ( $R^1 = R^2 = H, CH_3 = Ph$ ) is completely rearranged after 10-min boiling in 98–100% formic acid, and the olefin II ( $R^1 = R^2 = H$ ) after 3 hr-boiling, whereas the trisubstituted olefins II ( $R^1 = H$ ) are stable to boiling formic acid and require heating with dilute mineral acid before rearrangement can be effected. Presumably the ease of rearrangement is dependent on the ease of protonation of the double bond to give the carbonium ion IV, which can either revert to the olefin II with the loss of a proton, or can suffer ring fission to give the 14-alkenylcodeinone (V). Compounds of this structure V ( $R = Me$  and  $Ph$ ) have been isolated from the products of rearrangement of the alcohols I ( $R = Me$  and  $Ph$ ) and the derived olefins, and the ketone V ( $R = Ph, CH_3 = Et$ ) has been obtained from the alcohol I ( $R = Ph, CH_3 = Et$ ). In each of these cases, rearrangement to the codeinone was complete in refluxing 98–100% formic acid. In other cases, the alkenylcodeinones are only obtained when the alcohols or olefins are heated with dilute mineral acid. Under these conditions, however, the unsaturated ketones are themselves susceptible to further rearrangement (see following paper), and hence the yields of the codeinones in these cases are very poor, and the isolation of pure materials from the reaction mixtures is difficult.

The structures assigned to the 14-alkenylcodeinones (V) are in accord with their chemical properties and absorption spectra. They are insoluble in alkalis and do not couple with diazonium salts. Their infrared spectra show carbonyl absorption at  $1690\text{ cm}^{-1}$ , and the ultraviolet spectra of the bases V ( $R = Ph$  and also  $R = Ph, CH_3 = Et$ ) are styrenoid. The nmr spectrum of the base V ( $R = Ph$ ) shows signals (in  $\delta$  units) at 7.23 (five aromatic H), 6.52 (C-1 and C-2 H), doublets centered at 6.52 (C-8 H) and 6.05 (C-7 H) ( $J_{7,8} = 10$  cps), a triplet centered at 5.58 ( $CH=CMePh$ ), and singlets at 4.65 (OCH), 3.78 (C-3 OCH<sub>3</sub>), 2.40 (NCH<sub>3</sub>), and 2.02 ( $C=CPhCH_3$ ). The spectrum of the base V ( $R = Me$ ) is similar to that of the base ( $R = Ph$ ), but

<sup>1</sup> Part III: K. W. Bentley and D. G. Hardy, *J. Am. Chem. Soc.*, **89**, 1 (1967). (b) A preliminary report of part of this work has been given by K. W. Bentley and D. G. Hardy, *Proc. Chem. Soc.*, 220 (1963); the publication of this report some similar work on a simpler system has been reported by A. J. Birch and J. S. Hill, *J. Chem. Soc.*, 419 (1963).

<sup>2</sup> Part II: K. W. Bentley, D. G. Hardy, and B. Meek, *J. Am. Chem. Soc.*, **89**, 3273 (1967).

<sup>3</sup> K. W. Bentley and J. C. Ball, *J. Org. Chem.*, **23**, 1720 (1958).

lacks the signals at 7.23 and 2.02 and shows instead signals at 1.68 (3 H) and 1.47 (3 H) attributed to the methyl groups in the system  $C=CMe_2$ .

Catalytic reduction of the 14-alkenylcodeinones proceeds very sluggishly and affords poor yields of 14-alkyldihydrocodeinones (X), but isolation of pure materials is difficult since mixtures of isomers appear to be formed in most cases. Reduction only of the  $\alpha,\beta$ -unsaturated ketone system of the base V ( $R = Me$ ) could not be accomplished with zinc and acetic acid or with sodium amalgam, both of which reagents yielded mixtures containing phenols resulting from opening of the 4,5-oxygen bridge. The dihydro compound XI ( $R = Ph$ ) was, however, obtained, together with the alcohol XII ( $R = Ph$ ), by the reduction of the unsaturated ketone with sodium borohydride in pyridine.<sup>4</sup> The alkenyldihydrocodeinones XI are not accessible by the rearrangement of the 6,14-ethano alcohols analogous to those of structure I, since they appear to suffer further rearrangement in acid media very much more readily than their  $\alpha,\beta$ -unsaturated counterparts, and the rearrangements only furnish either olefins or phenolic bases. The C-6 carbonyl group in the 14-alkenylcodeinones and their reduction products can be reduced very readily with sodium borohydride to give the related derivatives of codeine, for example, the 14-alkenylcodeines (XII). In this reduction there is no evidence

(4) We are indebted to Dr. J. W. Lewis and Mr. M. J. Readhead of this laboratory for details of this reaction, the further implications of which will be discussed in a subsequent publication.

the 14-alkenylcodeinones and morphinones are, however, only intermediates in the complex rearrangements of the alcohols of structure I and their phenolic analogs undergo in acid media. When the alcohol I ( $R = \text{Me}$ ) is warmed at  $45^\circ$  with 6 *N* hydrochloric acid 6–7 hr or kept in the same medium at  $25^\circ$  for 3 days, it is converted in good yield into the 6-hydroxy analog ( $R = \text{Me}$ ), the infrared spectrum of which is very similar to that of the parent alcohol I ( $R = \text{Me}$ ) and shows no carbonyl absorption. The nmr spectrum shows no band attributable to the C-6 methoxyl group, but does show two bands at  $\delta$  4.71 and 4.48 that disappear after shaking the base with deuterium oxide and must, therefore, be due to two hydroxyl groups, the rest of the spectrum being virtually identical with that of the parent alcohol. Since the ketones III (also  $R = \text{Ph}$ ) are unaffected under the conditions under which the alcohol I ( $R = \text{Me}$ ) is demethylated, this demethylation may be assumed to proceed through the enylcodeinone V ( $R = \text{Me}$ ), by recyclization to the oxonium ion VI ( $R = \text{Me}$ ), which can then either lose a proton to give the 6-hydroxyolefin VIII, or react with a water molecule to give the alcohol VII ( $R = \text{Me}$ ). This process has, indeed, been accomplished separately starting with the codeinone V ( $R = \text{Me}$ ), which on heating in cold 6 *N* hydrochloric acid affords the alcohol VII ( $R = \text{Me}$ ) in good yield. The olefin VIII has not yet been isolated. Further support for this mechanism is forthcoming from the action of methyl formate, methanol, and perchloric acid on the enone V ( $R = \text{Me}$ ) which leads, presumably *via* a carbonium ion, to the carbinol methyl ether IX ( $R = \text{Me}$ ) (40%) and the olefin II ( $R^1 = R^2 = \text{H}$ ) (20%).<sup>6</sup> The alcohol VII ( $R = \text{Me}$ ) can be converted back into the alkenylcodeinone V ( $R = \text{Me}$ ) by heating in 100% formic acid.

From the alkenylcodeinone V ( $R = \text{Me}$ ), the alcohols VI ( $R = \text{Me}$ ) and VII ( $R = \text{Me}$ ), or the olefin II ( $R^1 = R^2 = \text{H}$ ) is heated with 6 *N* hydrochloric acid at  $100^\circ$  for a short period, further rearrangement occurs, and the major product is a phenolic base isomeric with the enone V ( $R = \text{Me}$ ) and, like the latter, an  $\alpha,\beta$ -unsaturated ketone. The phenolic hydroxyl must appear as the result of fission of the 4,5-oxide bridge, in which case a new bond must be formed to C-5, and the base is clearly an analog of flavonepentone (XV,  $R = \text{H}$ ,  $R^1 = \text{Ph}$ )<sup>3,7</sup> and may be assigned the structure XV ( $R = R^1 = \text{Me}$ ). This is supported by the nmr spectrum of the base which shows signals (in  $\delta$  units) at 3.5 (two aromatic H), doublets centered at 6.77 (C-8 H) and 5.67 (C-7 H) ( $J_{7,8} = 10$  cps), singlets at 4.42 (C-5 H), 2.36 (aromatic  $\text{OCH}_3$ ), 2.36 ( $\text{NCH}_3$ ) and 1.86 and 1.70 ( $\text{CMe}_2$ ), and by the ozonolysis of the base, which affords acetone.

The ultraviolet spectrum of the base XV ( $R = R^1 = \text{Me}$ ) further supports the assigned structure, showing as does the long wavelength absorption band  $\lambda_{\text{max}}$  3350 m $\mu$  which is a characteristic feature of the spectra of thebaone (XIX),<sup>8</sup> benzflavothebaone (XX),<sup>9</sup> and flavonepentone (XV,  $R = \text{H}$ ,  $R^1 = \text{Ph}$ ),<sup>3</sup> though the

intensity of absorption at this wavelength is somewhat less than in these three bases. This absorption band in flavothebaone has been attributed by Meinwald and Wiley<sup>10</sup> to charge transfer between the quinol nucleus and the enone system as shown in formula XXI, but such charge transfer is not possible in bases of general structure XV, in which no oxygen atom is available to supply electrons. Bentley, Dominguez, and Ringe,<sup>8</sup> however, have suggested that this long wavelength absorption band is simply the absorption band of the  $\alpha,\beta$ -unsaturated ketone system, which normally appears in this region but which in normal circumstances is very weak ( $\epsilon_{\text{max}} \sim 50$ ) intensified ( $\epsilon_{\text{max}} \sim 2000$ ) as a result of the perturbation of the enone system by the spatially proximate  $\pi$  orbitals of the unsaturated system, the precise nature of which (quinol, naphthaquinol, styrene, or isolated double bond) appears to be of little importance.

Bases of general structure XV can arise from the 14-alkenylcodeinones by protonation of the oxide bridge, bridge fission, and Markovnikov addition of the resulting carbonium ion to the side-chain double bond, as in XIII  $\rightarrow$  XV.<sup>8</sup> Non-Markovnikov addition, clearly unlikely, would lead to a base of structure XVI, which is demonstrably not that of the product. Alternatively, since the alkenylcodeinone is in equilibrium with the recyclized carbonium ion VI in acid solution, rearrangement may take place by way of such an ion and the olefin XVII, in which concerted bridge fission and migration in a pinacolone type rearrangement can occur. The geometry of the molecule of the olefin XVII is particularly favorable for such a 1,2 shift. In view of the formation of the olefin II from the carbonium ion IV, the ion XIV might be expected to give the olefin XVIII instead of the actual product XV.

Other bases analogous to the base XV ( $R = R^1 = \text{Me}$ ), bearing substituents other than a methyl group on the nitrogen atom, are preparable in about 40–50% yield by the rearrangement of the corresponding analogs of the alcohol I ( $R = \text{Me}$ ), and the related 3-hydroxy compounds may be obtained either by the demethylation of the 3-methoxy bases with 48% hydrobromic acid or by the combined rearrangement and demethylation of the appropriate alcohol with this reagent.

Zinc and acetic acid reduction of the unsaturated ketone XV ( $R = R^1 = \text{Me}$ ) affords the saturated ketone,<sup>11</sup> which is the sole end product of the rearrangement of the 6,14-ethano analog of the alcohol I ( $R = \text{Me}$ ). In this reaction, the 14-alkenylidihydrocodeinone (X,  $R = \text{Me}$ ) has not been detected as an intermediate in the reaction and it may be concluded that this base is rearranged more rapidly than the corresponding codeinone.

During the rearrangement of the alcohol I ( $R = \text{Me}$ ) and the codeinone V ( $R = \text{Me}$ ), a second process competes with the formation of the phenol XV ( $R = R^1 = \text{Me}$ ) giving rise to an isomer of the latter. This process,

(10) J. Meinwald and G. A. Wiley, *J. Am. Chem. Soc.*, **79**, 2569 (1957).

(11) 14-Hydroxycodeinone undergoes bimolecular coupling during reduction with zinc and acetic acid [L. J. Sargent and U. Weiss, *J. Org. Chem.*, **25**, 987 (1960)], but the enone system present in the bases of general structure XV is so shielded by the other parts of the molecule that bimolecular coupling is very seriously hindered. In the 14-alkenylcodeinones of structure V the enone system is much less hindered, and bimolecular coupling may be assumed to be involved in part in the formation of the very complex product of reduction of these bases with zinc and acetic acid.

We are indebted to Dr. J. J. Brown of Lederle Laboratories, Pearl River, N. Y., for details of this reaction.

(8) K. W. Bentley and J. C. Ball, *J. Org. Chem.*, **23**, 1725 (1958).

which is discussed in the following paper,<sup>12</sup> becomes the dominant one in the rearrangement of alcohols I in which R is not a methyl group, with the result that bases of structure XV then become minor products of the reaction. For example, the rearrangement of the alcohol I (R = Ph) affords only 1.6% of the phenol XV (R = Me, R' = Ph). This competing reaction, however, involves the 14-alkenylcodeinone (V) as an essential intermediate and is not operative in the rearrangement of the 6,14-ethano alcohols. Rearrangement of the alcohols XXII (R = *n*-Pr), XXII (R = *n*-Bu), XXII (R = *n*-Am), however, affords mixtures in each case of two isomeric phenols. The products from the alcohol XXII (R = *n*-Bu) have identical infrared spectra, and these are presumably *cis-trans* isomers XXIII and XXIV, which could obviously arise from the intermediate carbonium ion, whether this be of the type XIV or VI.

The presence of the carbonyl group in the alkenylcodeinone V (R = Me) is essential for the rearrangement of this base to the phenol XV (R = R' = Me) by recyclization to the carbonium ion VI and concerted oxide bridge opening and rearrangement as in XVII, and may be necessary for activation of the 4,5-oxide bridge if the rearrangement proceeds as shown in formulas XIII  $\rightarrow$  XV. The reaction of the 14-alkenyl-

codeine (XII, R = Me), which contains no carbonyl group, with hot concentrated hydrochloric acid was accordingly examined. This reaction yielded a complex mixture of products from which a crystalline base "A," mp 200°, was recovered in 25% yield. Base "A" is isomeric with the codeine XII (R = Me), and infrared spectrum shows carbonyl absorption at 17  $cm^{-1}$  but no hydroxyl absorption. It is very sparingly soluble in ethanol but dissolves readily on the addition

(12) Part V: K. W. Bentley, D. G. Hardy, C. F. Howell, W. Fulmor, J. E. Lancaster, J. J. Brown, G. O. Morton, and R. A. Hardy, Jr., *J. Am. Chem. Soc.*, **89**, 3303 (1967).

of sodium ethoxide to give a deep yellow solution, which couples readily with diazotized sulfanilic acid to give a blood red solution. Base "A" is recovered from the yellow ethoxide solution on the addition of water, but the addition of an excess of ammonium chloride solution results in the precipitation of a new base "B," which is isomeric with base "A" and shows phenolic hydroxyl absorption and carbonyl absorption at  $1690\text{ cm}^{-1}$  in the infrared. Base "B" is readily soluble in ethanol, and the solution rapidly deposits base "A" on the addition of a small amount of aqueous sodium hydroxide. The reduction of base "A" with sodium borohydride in neutral solution affords a nonphenolic alcohol, whereas reduction in the presence of sodium ethoxide yields a phenolic alcohol, and both of these products are stable to alkalis.

Base "A" reacts relatively slowly with bromine and, hence, cannot contain an olefinic center, and this is confirmed by the failure of ozonolysis to yield either acetone or formaldehyde. The nmr spectra of bases "A" and "B" show that both of these bases are aldehydes. Both spectra show signals attributable to the C-1 C-2 aromatic protons and protons of the  $\text{OCH}_3$ ,  $\text{NCN}_3$ , and two  $\text{CCH}_3$  groups. The two  $\text{CCH}_3$  peaks appear at  $\delta$  1.0 and 0.77 in the spectrum of base "A" and at  $\delta$  1.16 and 1.03 in the spectrum of base "B," indicating that neither base contains the system  $=\text{CMe}_2$ , and that some change in the distant environment of the two methyl groups occurs in the conversion of base "A" into base "B." The aldehyde proton signal in the spectrum of base "A" is a doublet at  $\delta$  9.35,  $J = 2$  cps, suggesting that the system  $>\text{CHCHO}$  is present in this base, whereas the corresponding signal in the spectrum of base "B" is a singlet at  $\delta$  9.76, which is consistent with the presence in this base of the system  $\text{C}=\text{CCHO}$ . This interpretation is consistent with the shift of carbonyl absorption frequency from  $1730$  to  $1690\text{ cm}^{-1}$  in the conversion of base "A" into base "B." The reversible conversion of the system  $\text{CCHCHO}$  into  $\text{C}=\text{CCHO}$  with the simultaneous appearance of a phenolic hydroxyl group suggests that base A and base B are related as shown in part structures XXV and XXVI, and in agreement with this the C-5 proton of XXV is revealed in the nmr spectrum of base A by a doublet centered at  $\delta$  5.15,  $J_{5,6} = 9$  cps, which is absent from the spectrum of base B. The spectrum of base B, however, shows a one-proton signal at  $\delta$  7.68, which is absent from the spectrum of base A and is attributable to the C-5 proton in XXVI.

The spectrum of base A shows no signal attributable to an olefinic proton and, hence, both of the double bonds in the base XII ( $\text{R} = \text{Me}$ ) must be involved in a cyclization process, in which case the side-chain methyl groups would appear as a *gem*-dimethyl group in the product. The appearance of an aldehyde group in base A indicates the contraction of ring C of XII and

all of these requirements are met by the mechanism shown in formulas XXVII  $\rightarrow$  XXIX. The resulting structures for base A XXIX and base B XXX are in agreement with all of the known facts about these bases. A model of the structure XXIX, which can be constructed with very little strain, shows that steric hindrance is least with the  $\text{CHO}$  group disposed on the same side of the molecule as the oxide bridge, and it may be noted that the infrared spectrum of the alcohol XXXI derived from base A shows a band attributable to a hydrogen-bonded hydroxyl group and that hydrogen bonding is easily accommodated in the structure XXXI but is impossible in the epimeric structure XXXII.

The primary alcohol XXXIII, obtained by the reduction of base A in sodium ethoxide solution, might be expected to suffer dehydration in acids by the mechanism shown, with 4,5-oxide ring closure, to give the olefin XXXIV, by analogy with the way in which both isomers of the dienol XXXV are cyclized to thebaine.<sup>13-14</sup>

(15) L. Knorr and H. Horlein, *ibid.*, 41, 969 (1908).

(16) The numbering of the ring system is given in structure XV. The 5,14-ethano bridge is on the same side of the molecule as are the hydrogen atoms at C-5 and C-14 in thebainone, as is implied by the nomenclature used.

The alcohol is recovered unchanged from hot dilute hydrochloric acid but on heating with concentrated hydrochloric acid is converted into a crystalline base that shows no hydroxyl absorption in the infrared but does show nmr signals (in  $\delta$  units) at 6.67 (two aromatic H), 3.92 (C-3 OCH<sub>3</sub>), 2.46 (NCH<sub>3</sub>), 1.07 (6 H, 2CH<sub>3</sub>), a complex one-proton signal at 5.60 (C-5 H, split by the methylene protons), and a two-proton doublet at 4.95 showing further splitting, due to the system CHC(=CH<sub>2</sub>)CH. There is little doubt that this base has the structure XXXIV.

The alkenylcodeine XXXVI, which is an analog of the base XXVII, on heating with concentrated hydrochloric acid gave a mixture from which about 10% of a crystalline solid was easily isolated. This base was isomeric with the codeine XXXVI, but the infrared spectrum showed no carbonyl group absorption. It did not react readily with bromine, and the nmr spectrum showed no signal attributable to an olefinic proton. This spectrum showed signals (in  $\delta$  units) at about 7.2 (phenyl group protons), 6.72 (C-1 and C-2 H), 4.70 (doublet, C-5 H,  $J_{5,6} = 9$  cps), 3.92 (C-3 OCH<sub>3</sub>), 3.05 (2 H), 2.40 (NCH<sub>3</sub>), and 1.39 (PhCCH<sub>3</sub>). It is clear from this spectrum that both of the double bonds present in the codeine XXXVI have disappeared with the conversion of the system CH=CMePh into C—(C)—CMePh during the production of this new base, and a rational interpretation of this is that the reaction proceeds through the cyclized carbonium ion XXXVII, which is an analog of the ion XXVIII.

This carbonium ion could be converted into a neutral product in several ways, e.g., by the loss of a proton from C-6 or C-8, by reaction with a water molecule to give a glycol, by ring contraction to give an aldehyde similar to the aldehyde XXIX, or by the loss of a proton from the hydroxyl group with the formation of an epoxide ring XXXVIII. Since the infrared spectrum of the base shows neither carbonyl nor hydroxyl group absorption, and the nmr spectrum shows no signal attributable to olefinic or hydroxyl protons, only the structure XXXVIII seems tenable for this compound. The complex two-proton signal at about  $\delta$  3.05 in the nmr spectrum of the base may be attributed to the protons at C-6 and C-7.

The base is recovered unchanged after treatment with lithium aluminum hydride or acetic anhydride, and is

attacked only very slowly by potassium periodate in 2 *N* sulfuric acid. The examination of models of the structure XXXVIII and its C-5' diastereoisomer shows that in both structures attack from above the molecule at C-7 by a hydride ion (which gives an axial C-6 hydroxyl group in the product) is very severely hindered by the methyl or phenyl group at C-5'. Also, although the oxygen atom of the epoxide ring may be attacked by a solvated proton, completion of the reaction with the formation of a *trans*-diaxial 6,7-glycol is very severely hindered by the C-5' substituent. The stability of the base to the reagents cited above is thus explicable on the basis of the structure XXXVIII.

It may be assumed that the acid-catalyzed rearrangements of the codeines XXVII and XXXVI are complex processes leading to a variety of products, the aldehyde XXIX and the epoxide XXXVIII simply being the most easily crystallized reaction products in the two cases.

The dehydration of the alcohols I to the olefins II and rearrangement to the 14-alkenylcodeinones (V) results in a substantial decrease in analgesic potency, but further transformation into the analogs of flavone-penthone results in the production of bases of high potency. For example, the base XV ( $R = R' = \text{Me}$ ) is about twice as potent and its methyl ether is about 15 times as potent as morphine.

## Experimental Section

**6,14-endo-Ethno-7 $\alpha$ -isopropenyltetrahydrothebaine (II,  $R^1 = R^2 = \text{H}$ ) (Anhydro-19-methylthevinol).** a. 6,14-endo-Ethno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (I,  $R = \text{Me}$ , 19-methylthevinol) (10 g) was boiled under reflux with 98–100% formic acid (25 ml) for 45 min. The mixture was diluted with ice-water (100 ml) and basified with ammonia, and the product was isolated by ether extraction. The dried extract was evaporated, and the residue was dissolved in benzene (250 ml) and passed down a column of grade 1 neutral alumina (75 g). A yellow band rapidly developed on the column, which was eluted with benzene until this band just reached the foot of the column. The eluate was concentrated and rechromatographed on alumina with elution again only of material running in front of the (narrow) yellow band. Evaporation of the eluate *in vacuo* gave a crystalline residue (3.8 g) which was recrystallized from methanol when the olefin was obtained as white irregular plates, mp 151°.

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>2</sub>: C, 76.0; H, 7.7. Found: C, 75.7; H, 7.5.

The hydrochloride, prepared in ethanol-ether had mp 198–200°. Elution of the yellow band on the alumina column with benzene containing 5% of chloroform gave 3.8 g of 14-(3-methylbut-2-enyl)codeinone (V,  $R = \text{Me}$ ) (see below).

Methyltriphenylphosphonium bromide (3.6 g, 0.01 mole) led to a solution of butyllithium (0.01 mole) in hexane-ether in atmosphere of nitrogen, and the mixture was stirred at temperature for 4 hr. 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahebaïne (III, 3.8 g) in dry ether (100 ml) was added to the orange solution, and the mixture was then stirred at temperature overnight. Solid matter was removed from the mixture by filtration and washed well with ether; the filtrate and washings were then washed with water, dried, and evaporated. The residue was crystallized from petroleum ether (bp 40–60°), and the product was shown by thin layer chromatography to be approximately a 3:1 mixture of the olefin II (R<sup>1</sup> = R<sup>2</sup> = H) and ketone III. Chromatographic separation of the two was done on a silica column, from which the olefin was first and was obtained on recrystallization from methanol as white prisms, mp 151°, alone or mixed with material prepared from alcohol I (R = Me) as in a above. Use of a 50% excess of ylide resulted in no improvement in the yield of olefin, and the ylide was generated with sodium hydride in dimethyl ether; the yield of olefin was reduced, since base-catalyzed rearrangement of the ketone also took place.

**Ozonolysis of Anhydro-19-methylthevinol (II, R<sup>1</sup> = R<sup>2</sup> = H).** Ozonized oxygen, with an ozone delivery rate of 0.5 mmole of ozone/min, was passed into a solution of anhydro-19-methylthevinol (1 mmole) in 4 N acetic acid (50 ml) cooled in ice water. 2 min, when 2.1 mmoles of ozone had been absorbed, zinc dust was added to the solution, which was shaken for 5 min, filtered, and neutralized with sodium bicarbonate, and then warmed. All evolved gas was drawn through a solution of 2,4-dinitrophenylhydrazine in dilute sulfuric acid, in which a precipitate of 2,4-dinitrophenylhydrazone, mp and mmp (with an authentic specimen) 166°, was formed.

A second ozonolysis with ozone uptake was limited to 1 mmole of the neutralization with sodium bicarbonate the mixture was extracted with ether. The ether extract on evaporation afforded from which on chromatographic separation on silica the mp 151°, and 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaïne, 1°, were recovered. The aqueous phase after the ether extraction on treatment with dimedone gave the formaldehyde derivative, mp 186°, undepressed on mixing with an authentic specimen.

**6,14-endo-Etheno-7 $\alpha$ -(1-phenylvinyl)tetrahydrothebaïne (Anhydro-19-phenylthevinol, II, R<sup>1</sup> = R<sup>2</sup> = H, CH<sub>2</sub> = Ph).** 6,14-endo-Etheno-7 $\alpha$ -(1-(R)-hydroxy-1-phenylethyl)tetrahydrothebaïne (I, R = Ph) (10 g) was dissolved in boiling 98–100% formic acid (25 ml), and the solution was boiled for 1.5 min and then poured into ice-water. The solution was basified with ammonia; the product was isolated by ether extraction and was chromatographed on grade 1 neutral alumina in benzene solution. The product was eluted with benzene, and the eluate was collected until the yellow band reached the foot of the column. Evaporation of the solvent *in vacuo* and recrystallization of the product from methanol gave the olefin (1.8 g) as pale fawn plates, mp 145–146°.

*Anal.* Calcd for C<sub>29</sub>H<sub>31</sub>NO<sub>2</sub>: C, 79.0; H, 7.1. Found: C, 78.1; H, 7.1.

On treatment of the yellow band from the alumina column with benzene containing 5% of chloroform afforded 5.3 g of 14-(3-phenylvinyl)codeinone, mp 168–169° (see below).

**6,14-endo-Ethano-7 $\alpha$ -isopropenyltetrahydrothebaïne (Anhydro-19-methylthevinol, II, R<sup>1</sup> = R<sup>2</sup> = H, 6,14-ethano).** 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaïne (di-19-methylthevinol, 2.0 g) was boiled under reflux with 98–100% formic acid for 10 min. The mixture was diluted with water, and extracted with ammonia, and extracted with ether. The dried ether on evaporation gave a viscous residue which was chromatographed on alumina in benzene solution with elution with benzene containing 5% of ethyl acetate until the presence of a second base eluate was just detectable by thin layer chromatography. The eluate was then evaporated, and the residue was crystallized from petroleum ether (bp 40–60°), when the olefin was obtained as prisms, mp 127°.

*Anal.* Calcd for C<sub>24</sub>H<sub>31</sub>NO<sub>2</sub>·0.5H<sub>2</sub>O: C, 73.9; H, 8.2. Found: C, 73.9; H, 8.2.

**6,14-endo-Ethano-7 $\alpha$ -isopropyltetrahydrothebaïne (Dihydro-19-thevinan).** 6,14-endo-Etheno-7 $\alpha$ -isopropylpenyltetrahydrothebaïne (anhydro-19-methylthevinol, 1.0 g) was shaken under nitrogen at 22° (760 mm) in the presence of 5% palladium on charcoal (250 mg) until absorption of hydrogen (130 ml, 2 mmole) ceased (3 hr). The solution was filtered from catalyst and concentrated, when the saturated base was obtained as an uncrystal-

lizable viscous gum characterized as the picrate, which was obtained as yellow needles, mp 194°, from 2-ethoxyethanol.

*Anal.* Calcd for C<sub>24</sub>H<sub>31</sub>NO<sub>2</sub>·C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>: C, 58.9; H, 5.9; N, 9.2. Found: C, 58.9; H, 5.9; N, 9.4.

**6,14-endo-Etheno-7 $\alpha$ -(1-methylprop-1-enyl)tetrahydrothebaïne (Anhydro-19-ethylthevinol, II, R<sup>1</sup> = H, R<sup>2</sup> = Me).** a. 6,14-endo-Etheno-7 $\alpha$ -(1-(R)-hydroxy-1-methylpropyl)tetrahydrothebaïne (19-ethylthevinol, I, R = Et) (1 g) was heated at 100° with 98–100% formic acid (10 ml) for 2 hr. The solution was diluted with ice-water and basified with ammonia. The product was isolated by ether extraction and crystallized and recrystallized from aqueous methanol when the olefin (II, R<sup>1</sup> = H, R<sup>2</sup> = Me) (0.6 g) was obtained as white irregular plates, mp 120–121°.

*Anal.* Calcd for C<sub>25</sub>H<sub>33</sub>NO<sub>2</sub>: C, 76.4; H, 7.9. Found: C, 76.7; H, 8.0.

b. 6,14-endo-Etheno-7 $\alpha$ -(1-(S)-hydroxy-1-methylpropyl)tetrahydrothebaïne (I, R = Me; Me = Et) (1 g) was dehydrated in the same way and gave the same olefin, melting point and mixture melting point with material prepared as in part a, 120–121°.

**6,14-endo-Etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydrothebaïne (Anhydro-9-propylthevinol, II, R<sup>1</sup> = H, R<sup>2</sup> = Et).** 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylbutyl)tetrahydrothebaïne (19-propylthevinol, I, R = n-Pr) (10 g) was boiled under reflux with 98–100% formic acid (50 ml) for 3 hr. The mixture was diluted with ice-water and basified with ammonia, and the product was isolated by ether extraction. On crystallization and recrystallization from aqueous methanol, the olefin II (R<sup>1</sup> = H, R<sup>2</sup> = Et) (6.8 g) was obtained as white plates, mp 110°.

*Anal.* Calcd for C<sub>28</sub>H<sub>35</sub>NO<sub>2</sub>: C, 76.7; H, 8.2. Found: C, 76.7; H, 8.3.

The same olefin was obtained by the dehydration in the same way of 6,14-endo-etheno-7 $\alpha$ -(1-(S)-hydroxy-1-methylbutyl)tetrahydrothebaïne, which is the C-19 epimer of the alcohol I (R = n-Pr).

**Ozonolysis of Anhydro-19-propylthevinol (II, R<sup>1</sup> = H, R<sup>2</sup> = Et).** Ozonized oxygen, delivering 0.6 mmole of ozone/min, was passed into a solution of anhydro-19-propylthevinol (0.41 g, 1 mmole) in 4 N acetic acid (50 ml). The reaction was stopped when 2 mmoles of ozone had been absorbed (8 min), and the reaction mixture was reduced with zinc dust, filtered, and neutralized with sodium bicarbonate. The neutralized solution was divided into two parts, one of which was warmed, and the evolved gas was passed through a solution of 2,4-dinitrophenylhydrazine in dilute sulfuric acid, when a 2,4-dinitrophenylhydrazone, mp 146°, was obtained. This depressed the melting point of pentan-2-one dinitrophenylhydrazone (mp 142°) but did not depress the melting point of propionaldehyde dinitrophenylhydrazone (mp 146°). The second portion of the neutralized reaction mixture was treated with dimedone, when the propionaldehyde derivative was obtained, mp 154° undepressed on mixing with an authentic specimen (mp 155°).

**6,14-endo-Etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydrothebaïne (Anhydro-19-propyldihydrothevinol, II, R<sup>1</sup> = H, R<sup>2</sup> = Et, 6,14-etheno).** a. 6,14-endo-Ethano-7 $\alpha$ -(1-(R)-hydroxy-1-methylbutyl)tetrahydrothebaïne (5 g) and 98–100% formic acid (100 ml) were boiled together under reflux for 20 min. The solution was diluted with ice-water and basified with ammonia, and the product was isolated by ether extraction and chromatographed on neutral alumina in benzene solution. Elution of the column with benzene:ethyl acetate, 95:5, gave the olefin (3 g) as white plates, mp 65–67°, from petroleum ether (bp 40–60°) characterized as the hydrochloride, mp 218–219°.

*Anal.* Calcd for C<sub>26</sub>H<sub>35</sub>NO<sub>2</sub>·HCl: C, 70.0; H, 8.1; Cl, 7.95. Found: C, 69.6; H, 8.1; Cl, 8.3.

b. 6,14-endo-Etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydrothebaïne (1 g) was hydrogenated at 20° (760 mm) over 5% palladium on charcoal (0.25 g) in ethanol. Hydrogen (50 ml, 1 mole) was absorbed over 90 min. Evaporation of the solution afforded an oil giving a hydrochloride, mp 218–219°, identical in melting point, mixture melting point, and infrared absorption with that obtained as in part a above.

**Other Olefins.** The following olefins were prepared by the same process as the one described above for the preparation of 6,14-endo-etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydrothebaïne: 6,14-endo-etheno-7 $\alpha$ -(1-methylpent-1-enyl)tetrahydrothebaïne (anhydro-19-butylthevinol, II, R<sup>1</sup> = H, R<sup>2</sup> = n-Pr, white plates, mp 75°, from methanol. *Anal.* Calcd for C<sub>27</sub>H<sub>35</sub>NO<sub>2</sub>: C, 77.0; H, 8.4. Found: C, 76.9; H, 8.4); 6,14-endo-etheno-7 $\alpha$ -(1-methylhex-1-enyl)tetrahydrothebaïne (anhydro-19-amylthevinol, II, R<sup>1</sup> = H, R<sup>2</sup> = n-Bu, white plates, mp 180°, from methanol. *Anal.* Calcd for C<sub>28</sub>H<sub>37</sub>NO<sub>2</sub>·0.5H<sub>2</sub>O: C, 75.7; H, 8.6. Found: C, 75.6; H, 8.3); 6,14-endo-etheno-7 $\alpha$ -(1,4-dimethylpent-1-enyl)-

tetrahydrothebaine (anhydro-19-isoamylthevinol, II,  $R^1 = H$ ,  $R^2 = i\text{-Bu}$ , noncrystalline, hydrochloride, white prisms, mp  $170^\circ$ , from water. *Anal.* Calcd for  $C_{28}H_{33}NO_3 \cdot HCl \cdot H_2O$ : C, 71.5; H, 8.5. Found: C, 71.4; H, 8.4; N-(2-methylallyl)-6,14-endo-etheno-7 $\alpha$ -(1-methylprop-1-enyl)tetrahydronorthebaine (N-methylallylanhydro-19-ethylnorthevinol, II,  $R^1 = H$ ,  $R^2 = Me$ , NMe =  $NCH_2CMe=CH_2$ , white plates, mp  $110^\circ$ , from methanol. *Anal.* Calcd for  $C_{28}H_{33}NO_3$ : C, 77.6; H, 8.2. Found: C, 77.5; H, 8.2). N-propargyl-6,14-endo-etheno-7 $\alpha$ -(1-methylpent-1-enyl)tetrahydronorthebaine (N-propargylanhydro-19-butylnorthevinol, II,  $R^1 = H$ ,  $R^2 = n\text{-Pr}$ , NMe =  $NCH_2C\equiv CH$ , white plates, mp  $108^\circ$ , from methanol. *Anal.* Calcd for  $C_{29}H_{33}NO_3 \cdot 0.5H_2O$ : C, 76.7; H, 7.9. Found: C, 76.7; H, 7.9; and, 6,14-endo-etheno-7 $\alpha$ -(1-methylprop-1-enyl)tetrahydrothebaine (anhydro-19-ethylidihydrothevinol, II,  $R^1 = H$ ,  $R^2 = Me$ , 6,14- $CH_2CH_2$ , noncrystalline, hydrochloride white prisms, mp  $222\text{--}223^\circ$ , from ethanol. *Anal.* Calcd for  $C_{25}H_{29}NO_3 \cdot HCl \cdot 0.5H_2O$ : C, 69.5; H, 7.9; Cl, 8.2. Found: C, 68.2; H, 8.1; Cl, 8.4).

N-Cyano-6,14-endo-etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydronorthebaine (N-Cyanoanhydro-19-propylnorthevinol, II,  $R^1 = H$ ,  $R^2 = Et$ , NMe = CN). The olefin II ( $R^1 = H$ ,  $R^2 = Et$ ) (5 g), cyanogen bromide (2 g), and methylene chloride (100 ml) were boiled together under reflux for 24 hr. Evaporation of the solvent and crystallization of the residue from methanol afforded the N-cyanonor compound (4 g) as prisms, mp  $138^\circ$ .

*Anal.* Calcd for  $C_{25}H_{29}N_3O_3$ : C, 74.7; H, 7.2. Found: C, 75.0; H, 7.2.

6,14-endo-Etheno-7 $\alpha$ -(1-methylbut-1-enyl)tetrahydroorpavine. 6,14-endo-Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-methylbutyl)tetrahydroorpavine (19-propylorvinol, I,  $R = n\text{-Pr}$ , 3OMe = 3OH) (2 g) was heated at  $100^\circ$  with 98–100% formic acid (20 ml) for 2 hr. The mixture was diluted with ice-water and basified with ammonia and the product collected. It was not immediately soluble in dilute aqueous sodium hydroxide, and the infrared spectrum showed a carbonyl absorption band at  $1730\text{ cm}^{-1}$ . It was evidently the 3-O-formyl ester of the phenol and was hydrolyzed by heating to boiling for 2 min with potassium hydroxide (0.25 g) in ethanol (10 ml). The solution was diluted with water, and the phenol was precipitated with aqueous ammonium chloride and isolated by ether extraction. The resulting viscous gum was dissolved in ethanol (5 ml) made acid with ethanolic hydrogen chloride and diluted with ether when the hydrochloride crystallized. This was collected and recrystallized from ethanol-ether and was obtained as prisms, mp  $122^\circ$ .

*Anal.* Calcd for  $C_{25}H_{27}NO_3 \cdot HCl \cdot 0.5H_2O$ : C, 68.5; H, 7.6. Found: C, 68.2; H, 7.7.

14-(3-Methylbut-2-enyl)codeinone (V,  $R = Me$ ). a. 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (19-methylthevinol, I,  $R = Me$ ) (10 g) was boiled under reflux for 3 hr with 98–100% formic acid (30 ml). The solution was diluted with ice-water and basified with ammonia. The product was collected, washed well with water, air dried, and recrystallized from methanol, when the codeinone (6.5 g) was obtained as pale cream prisms, mp  $139\text{--}140^\circ$ ,  $\nu_{max}$   $1690\text{ cm}^{-1}$ .

*Anal.* Calcd for  $C_{25}H_{27}NO_3$ : C, 75.6; H, 7.5. Found: C, 75.4; H, 7.4.

The hydrochloride formed prisms, mp  $286\text{--}288^\circ$ . The base was insoluble in aqueous sodium hydroxide, and in methanolic sodium hydroxide solution gave no color with diazotized sulfanilic acid.

b. 6,14-endo-Etheno-7 $\alpha$ -isopropenyltetrahydrothebaine (II,  $R^1 = R^2 = H$ ) (1 g) was boiled with 98–100% formic acid (15 ml) for 3 hr. Isolation of the product as in part a gave 0.75 g of the same codeinone, mp  $139\text{--}140^\circ$ .

N-Propargyl-14-(3-methylbut-2-enyl)norcodeinone (V,  $R = Me$ , NMe =  $NCH_2C\equiv CH$ ). Prepared as above from N-propargyl-6,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydronorthebaine (N-propargyl-19-methylnorthevinol, I,  $R = Me$ , NMe =  $NCH_2C\equiv CH$ ) this base was obtained as prisms, mp  $126^\circ$ , from methanol.

*Anal.* Calcd for  $C_{25}H_{27}NO_3$ : C, 77.2; H, 7.2. Found: C, 77.2; H, 7.0.

N-(3,3-Dimethylallyl)-14-(3-methylbut-2-enyl)norcodeinone (V,  $R = Me$ , NMe =  $NCH_2CH=CMe_2$ ). Prepared as above from N-(3,3-dimethylallyl)-19-methylnorthevinol (I,  $R = Me$ , NMe =  $NCH_2CH=CMe_2$ ) this base was obtained as prisms, mp  $123^\circ$ , from methanol.

*Anal.* Calcd for  $C_{27}H_{33}NO_3$ : C, 77.4; H, 7.9. Found: C, 77.5; H, 7.8.

Ozonolysis of 14-(3-Methylbut-2-enyl)codeinone (V,  $R = Me$ ). Ozonized oxygen, delivering 0.5 mmole of ozone/min was passed

into a solution of 14-(3-methylbut-2-enyl)codeinone (1 mmole) in 4 *N* acetic acid (50 ml). 7.2 mmoles of ozone had been absorbed with zinc dust, filtered, neutralized, warmed. The evolved gas was passed through phenylhydrazine in dilute sulfuric acid (0.182 g, 0.7 mmole) and 125 $^\circ$  undepressed on mixing with an equal volume of water.

14-(3-Methylbut-2-enyl)codeinone (X) (0.5 g), 14-(3-methylbut-2-enyl)codeinone (10 g), and 2-ethoxyethanol (30 ml) reflux for 15 min. Water was added and crystalline material began to separate initially but dissolved. The mixture was cooled in ice-water, recrystallized from aqueous 2-ethoxyethanol, and white plates, mp  $111^\circ$ . *Anal.* Calcd for  $C_{25}H_{27}NO_3$ : C, 75.5; H, 8.0.

7,8-Dihydro-14-(3-methylbut-2-enyl)codeinone (V,  $R = H$ ) was hydrogenated at  $22^\circ$  (750 mm) in ethanol on charcoal (250 mg). Hydrogen (2 g) over 75 min. Filtration and evaporation of the dihydrocodeinone as a viscous gum for several weeks. Trituration of the ice-cold methanol afforded prisms, mp  $174^\circ$ . *Anal.* Calcd for  $C_{25}H_{29}NO_3$ : C, 74.6; H, 8.2.

14-(3-Phenylbut-2-enyl)codeinone Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-phenylethyl)codeinone (V,  $R = Ph$ ) (10 g) was heated under reflux (50 ml) for 30 min. The mixture was basified with ammonia. The precipitate from aqueous 2-ethoxyethanol, when the codeinone was obtained as white prisms, mp  $156\text{--}157^\circ$ ,  $\nu_{max}$   $1690\text{ cm}^{-1}$ ,  $\epsilon_{max}$  20,000 and 4000.

*Anal.* Calcd for  $C_{28}H_{29}NO_3$ : C, 78.6; H, 6.7.

The picrate formed yellow prisms, mp  $172^\circ$ .

*Anal.* Calcd for  $C_{28}H_{29}NO_3 \cdot C_6H_5N_3O_7$ : C, 63.0; H, 5.0; N, 8.5.

The oxime formed white prisms, mp  $170^\circ$ . *Anal.* Calcd for  $C_{28}H_{29}NO_3$ : C, 76.4; H, 7.0.

The same base was obtained by heating 14-(3-phenylbut-2-enyl)codeinone (9 g) at  $100^\circ$  with 2 *N* hydrochloric acid for 3 hr.

14-(3-Phenylbut-2-enyl)codeinone (X) (0.5 g), 14-(3-phenylbut-2-enyl)codeinone (10 g), and 2-ethoxyethanol (50 ml) reflux for 30 min. Water was added and the mixture was cooled in ice-water. The mixture was basified with ammonia and the product was collected and 2-ethoxyethanol, when the codeinone was obtained as white plates, mp  $172^\circ$ .

*Anal.* Calcd for  $C_{28}H_{29}NO_3$ : C, 78.2; H, 7.3.

7,8-Dihydro-14-(3-phenylbut-2-enyl)codeinone (V,  $R = Ph$ ) was hydrogenated at  $22^\circ$  (750 mm) in ethanol on charcoal (250 mg). Hydrogen (2 g) over 75 min. Filtration and evaporation of the dihydrocodeinone as a viscous gum for several weeks. Trituration of the ice-cold methanol afforded prisms, mp  $174^\circ$ . *Anal.* Calcd for  $C_{28}H_{29}NO_3$ : C, 78.4; H, 7.1.

Elution of the column with 50% ethanol gave the dihydro ketone XI ( $R = Ph$ ) from methanol as white elongated prisms, mp  $174^\circ$ .

*Anal.* Calcd for  $C_{28}H_{29}NO_3$ : C, 78.4; H, 7.1.

Elution of the column with 50% ethanol gave the dihydro ketone XI ( $R = Ph$ ) from methanol as white elongated prisms, mp  $174^\circ$ .

14-(3-Phenylbut-2-enyl)codeinone (X) (0.5 g), 14-(3-phenylbut-2-enyl)codeinone (10 g), and 2-ethoxyethanol (50 ml) reflux for 30 min. Water was added and the mixture was cooled in ice-water. The mixture was basified with ammonia and the product was collected and 2-ethoxyethanol, when the codeinone was obtained as white plates, mp  $172^\circ$ .

acid (8 ml) for 30 min. The base isolated in the usual way was recrystallized from aqueous 2-ethoxyethanol, when it was obtained as white prisms, mp 176–177°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{31}\text{NO}_2$ : C, 78.9; H, 7.0. Found: C, 78.3; H, 7.2.

**6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)dihydrocodeine (VII, R = Me).** a. 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (I, R = Me) (20 g) was heated at 45° with 6 *N* hydrochloric acid (160 ml) for 6 hr. The mixture was diluted, and the base was precipitated with ammonia, collected, and recrystallized from ethanol, when the dihydrocodeine derivative (13.3 g) was obtained as white prisms, mp 265°.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{33}\text{NO}_4$ : C, 72.0; H, 7.6; N, 3.7; OMe (1), 8.1. Found: C, 72.0; H, 7.6; N, 3.7; OMe, 8.0.

The hydrochloride was obtained as white prisms, mp 262°, from ethanol.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{33}\text{NO}_4 \cdot \text{HCl} \cdot \text{H}_2\text{O}$ : C, 63.1; H, 7.4. Found: C, 62.6; H, 7.5.

b. 14-(3-Methylbut-2-enyl)codeinone (V, R = Me) (1 g) was heated at 45° with 6 *N* hydrochloric acid (10 ml) for 6 hr. The base recovered as above was obtained as white prisms, mp 262° alone or mixed with material prepared as in a. The bases prepared by both methods had identical infrared spectra.

**6,14-endo-Etheno-7 $\alpha$ -(1-methoxy-1-methylethyl)tetrahydrothebaine (IX, R = Me).** a. Perchloric acid (1.5 ml, 72%) was added dropwise to a stirred solution of 14-(3-methylbut-2-enyl)codeinone (V, R = Me) (500 mg) in methylene chloride (10 ml), methanol (10 ml), and trimethyl orthoformate (10 ml), and the mixture was kept at room temperature for 20 hr. Methylene chloride was added, and the mixture was washed with aqueous sodium bicarbonate and water and dried. Thin layer chromatography showed the product to consist of one major and one minor, less polar, component. The gum obtained by the removal of solvent was dissolved in *n*-hexane, and the solution was chromatographed on alumina (20 g, Woelm, activity II). Fractions of 10 ml were collected and examined by thin layer chromatography. The column was eluted first with 5% and then with 10% chloroform in *n*-hexane, when the less polar component was eluted. The material (12 mg, c 2.5%) was identical in melting point (143–145°) and infrared absorption with 6,14-endo-etheno-7 $\alpha$ -isopropenyltetrahydrothebaine (II, R<sup>1</sup> = R<sup>2</sup> = H) obtained by the dehydration of the alcohol (I, R = Me). Continued elution of the column gave a mixture of the two components followed by the more polar component. The column was then eluted with 25 and 50% methylene chloride in *n*-hexane. Evaporation of appropriate fractions gave a gum which was crystallized from aqueous methanol to give 6,14-endo-etheno-7 $\alpha$ -(1-methoxy-1-methylethyl)tetrahydrothebaine (130 mg), mp 97–99°. A further 90 mg was obtained from the mother liquors making a total yield of 39%. The compound showed no carbonyl absorption in the infrared and had nmr signals (in  $\delta$  units) at 6.57 and 6.51 (C-1 H and C-2 H; doublets,  $J_{1,2}$  = 9 cps), 5.72 and 5.37 (C-18 H and C-17 H; doublets  $J_{17,18}$  = 10 cps), 4.56 (C-5 H), 3.82 (C-3 OMe), 3.58 (C-6 OMe), 3.18 (C-19 OMe), 2.36 (NMe), 1.30 and 0.95 (C-19 OMe).

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{31}\text{NO}_4$ : C, 73.0; H, 8.1; N, 3.4. Found: C, 72.5; H, 7.9; N, 3.5.

b. 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (19-methylthevinol, I, R = Me) (1 g) was added to a solution of potassiumamide (from 0.2 g of potassium) in liquid ammonia (~100 ml), and the mixture was stirred for 15 min. Methyl iodide (1 ml) was then added and the mixture stirred for 10 min more and poured cautiously into water (200 ml). The precipitated product was isolated by ether extraction and shown by thin layer chromatography to consist of approximately 30% of starting material (I, R = Me) and 70% of a less polar compound. The mixture was dissolved in a 1:1 mixture of benzene and *n*-hexane and chromatographed on a column of alumina (Woelm, activity II). The column was eluted with benzene, and 25-ml samples were collected, the composition of these being followed by thin layer chromatography. The first material to be eluted from the column (500 mg) was obtained as a gum, which crystallized on keeping for several hours. On recrystallization from aqueous methanol it was obtained as white prisms, mp 96–98°, identical in infrared absorption with material prepared as in part a above.

**5,14-Ethano-18-isopropylidenethebainone (XV, R = R<sup>1</sup> = Me).** a. 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (19-methylthevinol, I, R = Me) (50 g) was heated at 100° with 10 *N* hydrochloric acid (150 ml) for 45 min, during which time crystalline material separated. The mixture was diluted with water (150 ml) and cooled in ice, and the hydrochloride

(27 g) was collected. This was dissolved in aqueous methanol, and the base was precipitated with ammonia. It was recrystallized readily only from methanol, from which it separated as off-white solvated prisms, mp 138°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_3 \cdot 0.5\text{CH}_3\text{OH}$ : C, 73.0; H, 7.6. Found: C, 72.8; H, 7.8.

The hydrochloride was obtained as white prisms, mp 320°, from water.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_3 \cdot \text{HCl}$ : C, 68.7; H, 7.0. Found: C, 68.4; H, 7.2.

The picrate was obtained as yellow needles, mp 224°, from aqueous 2-ethoxyethanol.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{27}\text{NO}_3 \cdot \text{C}_6\text{H}_5\text{N}_2\text{O}_7 \cdot 1.5\text{H}_2\text{O}$ : C, 56.0; H, 5.2. Found: C, 55.8; H, 5.2.

b. The same base was obtained from 6,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)dihydrocodeine (VII, R = Me), from 6,14-endo-etheno-7 $\alpha$ -isopropenyltetrahydrothebaine (II, R<sup>1</sup> = R<sup>2</sup> = H), and from 14-(3-methylbut-2-enyl)codeinone (V, R = Me) by the same process as in a above, the yields being comparable with that in a in all cases.

The base was almost insoluble in aqueous alkalis but dissolved readily in aqueous methanolic potassium hydroxide to give an orange solution that readily coupled with diazotized sulfanilic acid to give a blood red solution. The alkaline solution was readily methylated and ethylated with methyl and ethyl sulfate, respectively.

The 4-O-methyl ether was prepared most conveniently from the hydrochloride obtained directly from the acid-catalyzed rearrangement of the alcohol (I, R = Me). The hydrochloride (20 g) was suspended in methyl sulfate (50 ml), and the mixture was cooled in ice. A solution of potassium hydroxide (40 g) in water (80 ml) was slowly added to the vigorously stirred suspension at a rate sufficient to keep the temperature of the mixture between 15 and 20°. When all of the alkali had been added, the mixture was stirred at 20° for 2 hr. Water (150 ml) was added, and the solid base was collected, washed, and recrystallized from methanol, when it was obtained as off-white prisms, mp 176–177°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{29}\text{NO}_3$ : C, 76.0; H, 7.7. Found: C, 76.0; H, 7.8.

The 4-O-ethyl ether was obtained from aqueous methanol as white prisms, mp 126–127°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{25}\text{H}_{31}\text{NO}_3$ : C, 76.4; H, 8.0. Found: C, 76.4; H, 7.9.

**Ozonolysis of 5,14-Ethano-18-isopropylidenethebainone (XV, R = R<sup>1</sup> = Me).** Ozonized oxygen, delivering 0.5 mmole of ozone/min was passed into a solution of 5,14-ethano-18-isopropylidenethebainone (0.365 g, 1 mmole) in 4 *N* acetic acid (50 ml). After 26 min, when 2 mmole of ozone had been absorbed, the mixture was reduced with zinc dust, filtered, neutralized with sodium bicarbonate, and warmed. The evolved gas was passed through a solution of 2,4-dinitrophenylhydrazine in dilute sulfuric acid, when acetone 2,4-dinitrophenylhydrazone (0.192 g, 0.807 mmole) was obtained, mp 125° alone or mixed with an authentic specimen.

**7,8-Dihydro-5,14-ethano-18-isopropylidenethebainone (XXIII, R = Me).** a. 6,14-endo-Ethano-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (dihydro-19-methylthevinol, XXII, R = Me) (2 g) was heated with 10 *N* hydrochloric acid (20 ml) for 2 hr at 100°. The mixture was diluted with water, and the base was precipitated with ammonia, collected, and recrystallized from methanol, when it was obtained as white prisms, mp 142°,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{29}\text{NO}_3$ : C, 75.2; H, 7.9. Found: C, 75.2; H, 7.8.

The hydrochloride formed prisms, mp 245°, from water.

*Anal.* Calcd for  $\text{C}_{23}\text{H}_{29}\text{NO}_3 \cdot \text{HCl} \cdot 1.5\text{H}_2\text{O}$ : C, 64.1; H, 7.7. Found: C, 64.1; H, 7.5.

b. Zinc dust (2 g) was added to a vigorously stirred boiling solution of 5,14-ethano-18-isopropylidenethebainone (V, R = R<sup>1</sup> = Me) in glacial acetic acid (25 ml) and water (2 ml). The mixture was stirred and heated under reflux for 2 hr, filtered, diluted with aqueous ammonium chloride, and basified with ammonia. The precipitated base was collected and recrystallized from methanol, when it was obtained as prisms identical in melting point, mixture melting point, and infrared absorption with material prepared as in part a above.

The 4-O-methyl ether, prepared by methylation of the phenol and by reduction of the corresponding thebainone methyl ether with zinc dust and acetic acid, was obtained as off-white prisms, mp 168–169°,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{31}\text{NO}_3$ : C, 75.6; H, 8.1. Found: C, 75.8; H, 8.0.

**N-Allyl-5,14-ethano-18-isopropylidenenorthebainone (XV, R = R' = Me, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>).** N-Allyl-7,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydronorthebaine (1 g) was heated 100° with 10 N hydrochloric acid (10 ml) for 2 hr. The mixture was diluted with water; the hydrochloride (0.38 g) was collected and recrystallized from aqueous methanol, when it was obtained as white prisms, mp 186–188°,  $\nu_{\max}$  1690 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>25</sub>H<sub>29</sub>NO<sub>3</sub>·HCl: C, 70.1; H, 7.0. Found: C, 70.2; H, 7.2.

The base could not be crystallized.

The following hydrochlorides were prepared from the appropriate N-substituted 6,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydronorthebaines, and hot concentrated hydrochloric acid with isolation of the sparingly soluble salt: N-propargyl-5,14-ethano-18-isopropylidenenorthebainone (XV, R = Me, NMe = NCH<sub>2</sub>C $\equiv$ CH, prisms, mp 155°. *Anal.* Calcd for C<sub>23</sub>H<sub>27</sub>NO<sub>3</sub>·HCl·H<sub>2</sub>O: C, 67.6; H, 6.8. Found: C, 68.0; H, 6.7); N-(3,3-dimethylallyl)-5,14-ethano-18-isopropylidenenorthebainone (XV, R = Me, NMe = NCH<sub>2</sub>CH=CMe<sub>2</sub>, prisms, mp 196°. *Anal.* Calcd for C<sub>27</sub>H<sub>33</sub>NO<sub>3</sub>·HCl·H<sub>2</sub>O: C, 68.3; H, 7.6. Found: C, 68.3; H, 8.0); and N-cyclopropylmethyl-5,14-ethano-18-isopropylidenenorthebainone (XV, R = Me, NMe = N-cyclopropylmethyl, white prisms, mp 206°. *Anal.* Calcd for C<sub>25</sub>H<sub>29</sub>NO<sub>3</sub>·HCl·H<sub>2</sub>O: C, 67.9; H, 7.4. Found: C, 67.8; H, 7.4).

**3-O-Desmethyl-5,14-ethano-18-isopropylidenethebainone (XV, R = R' = Me, OMe = OH).** a. 5,14-Ethano-18-isopropylidenethebainone (5 g) was boiled under reflux with 48% hydrobromic acid (50 ml) for 1 hr. Solid material that separated was dissolved by the addition of water (10 ml) and methanol (50 ml), and the solution was then basified with ammonia and the solid collected and recrystallized from methanol, when it was obtained as prisms (3 g), mp 268°.

*Anal.* Calcd for C<sub>22</sub>H<sub>25</sub>NO<sub>3</sub>: C, 75.2; H, 7.1. Found: C, 75.6; H, 7.0.

The hydrochloride was obtained as prisms, mp 342°, from aqueous methanol.

*Anal.* Calcd for C<sub>22</sub>H<sub>25</sub>NO<sub>3</sub>·HCl: C, 68.1; H, 6.7. Found: C, 68.0; H, 6.8.

b. The same base (2 g, identical in melting point and infrared absorption with the above) was obtained by the direct rearrangement and demethylation of 6,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (5 g) with 48% hydrobromic acid (45 ml). The hydrobromide was separated and dissolved in aqueous ethanol, and the base was precipitated with ammonia.

**N-Allyl-3-O-desmethyl-5,14-ethano-18-isopropylidenenorthebainone (XV, R = R' = Me, OMe = OH, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>).** N-Allyl-6,14-endo-etheno-7-(1-hydroxy-1-methylethyl)tetrahydronororipavine (N-allyl-19-methylnororvinol) (6 g) was heated under reflux with 4 N hydrochloric acid (40 ml) for 3 hr. The solid hydrochloride was collected, dissolved in aqueous methanol, and converted to the base with ammonia, the base being obtained from methanol as white prisms, mp 260° dec.

*Anal.* Calcd for C<sub>24</sub>H<sub>27</sub>NO<sub>3</sub>: C, 76.4; H, 7.3. Found: C, 76.2; H, 7.2.

**5,14-Ethano-18-(methylbenzylidene)thebainone (XV, R = Me, R' = Ph, Methylflavonepenthone).** 6,14-endo-Etheno-7 $\alpha$ -(1-(R)-hydroxy-1-phenylethyl)tetrahydrothebaine (I, R = Ph) (20 g) was heated with concentrated hydrochloric acid (75 ml) and ethanol (10 ml) at 100° for 30 min, during which time a crystalline hydrochloride separated. The mixture was diluted with water (100 ml) and thoroughly cooled in ice. The crystalline solid was collected. This consisted of the hydrochlorides of 7,8-dihydro-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone and the cyclohex-5'-eno isomer (see following paper), and a solution in aqueous methanolic sodium hydroxide gave only a pale pink color with diazotized sulfanilic acid.

The filtrate from the collection of this hydrochloride, which gave an intense diazo coupling reaction in alkaline solution, was basified with ammonia and the relatively small amount of gummy base produced was extracted rapidly with ether. The extract was shaken for 15 sec with magnesium sulfate and filtered. Rosettes of needles quickly separated from the ether solution and these were collected, washed well with ether, and recrystallized from aqueous 2-ethoxyethanol, when the thebainone derivative (320 mg) was obtained as off-white needles, mp 290°,  $\nu_{\max}$  1690 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>20</sub>H<sub>23</sub>NO<sub>3</sub>: C, 78.8; H, 6.8. Found: C, 78.7; H, 6.7.

The O-methyl ether was obtained as a crystalline precipitate on the addition of methyl sulfate (0.25 ml) to a solution of the phenol (100 mg) in methanol (3 ml), water (1 ml), and potassium hydroxide

(200 mg), and on recrystallization it was recovered, as almost white needles.

*Anal.* Calcd for C<sub>21</sub>H<sub>25</sub>NO<sub>3</sub>: C, 79.3; H, 7.0.

The O-ethyl ether, prepared in an analogous manner, was obtained from aqueous 144°.

*Anal.* Calcd for C<sub>23</sub>H<sub>29</sub>NO<sub>3</sub>: C, 79.3; H, 7.4.

**6 $\alpha$ -Formyl-5',5'-dimethylcyclopentan-2-one (Base A; XXIX).** 14-(3-Me) (5 g) was heated at 100° w acid (10 ml) for 45 min. The solution pink, and finally dark red brown. 1 water (40 ml) and basified with ammonia was washed three times with water 1 with hot methanol (35 ml), when a white solid was obtained. The suspension was cooled, and the solid with cold methanol, and recrystallized from ethanol when "base A" (1.5 g) was obtained as white prisms, mp 200°,  $\nu_{\max}$  1730 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>10</sub>H<sub>15</sub>NO<sub>3</sub>: C, 75.8; H, 7.9.

The base was very sparingly soluble in the presence of sodium hydroxide solution.

The perchlorate formed prisms, mp 144°.

*Anal.* Calcd for C<sub>10</sub>H<sub>15</sub>NO<sub>3</sub>·HClO<sub>4</sub>: C, 59.15; H, 6.4.

**6-Formyl-5',5'-dimethylcyclopentan-2-one (Base B; XXX).** Base B in ethanol (10 ml) containing sodium hydroxide, and the yellow solution was poured into an excess of water and the base was precipitated with water, and recrystallized from methanol as white felted needles, mp 144°.

*Anal.* Calcd for C<sub>10</sub>H<sub>15</sub>NO<sub>3</sub>: C, 75.6; H, 7.9.

The same base was obtained, less colorless solution of base A was precipitated. The base was readily soluble in water and the solution gave a deep red color with diazotized sulfanilic acid.

**Conversion of Base B (XXX) into Base A.** Base B was dissolved in methanol (1 ml) and sodium hydroxide was added. The solution on warming rapidly deposited base A, which was mixed with an authentic specimen.

**Reduction of Base A with Sodium Borohydride.** Sodium borohydride (50 mg) and sodium hydroxide (50 mg) were added to a solution of base A (100 mg) in ethanol (10 ml) until all the base was reduced. The product was isolated by ether extraction, when 6-(1-cyclopentyl-1',2':8,14)-(–)-sinomenil-5-ene (XXXIII) (1 g) was obtained as a viscous oil, characterized by its infrared spectrum, which was obtained as yellow needles.

*Anal.* Calcd for C<sub>10</sub>H<sub>15</sub>N<sub>2</sub>O<sub>4</sub>: C, 64.3; H, 6.0; N, 7.8.

**Reduction of Base A with Sodium Borohydride.** Sodium borohydride (150 mg) was added to a solution of base A (XXIX) (1 g) in ethanol (10 ml) and the mixture was warmed until the colorless solution was produced. The almost colorless solution was produced and the product isolated by ether extraction, when 6-(1-hydroxymethyl-5',5'-dimethylcyclopentan-2-yl)-sinomenil-5-ene (XXXIII) (1 g) was obtained as a colorless glass, bp 190–200°.

*Anal.* Calcd for C<sub>20</sub>H<sub>29</sub>NO<sub>3</sub>: C, 74.7; H, 8.0.

**6-Methylene-5',5'-dimethylcyclopentan-2-one (XXXIV).** 6-Hydroxymethyl-5',5'-dimethylcyclopentan-2-one (1 g) was boiled with concentrated hydrochloric acid (10 ml) and the mixture was diluted with water (100 ml) and the product, isolated by ether extraction, was recrystallized from ethanol in which it was obtained dissolved readily in

in which the noncrystalline matter was virtually insoluble. Concentration of the petroleum solution afforded the olefin XXXIV (75 mg) as white elongated prisms, mp 107–108°.

*Anal.* Calcd for  $C_{12}H_{20}NO_2$ : C, 78.6; H, 8.3. Found: C, 78.2; H, 8.2.

**Rearrangement of 14-(3-Phenylbut-2-enyl)codeine (XXXVI).** 14-(3-Phenylbut-2-enyl)codeine (XXXVI) (2 g) was heated at 100° in the water bath with concentrated hydrochloric acid (20 ml) for 45 min. The pink solution was then diluted with 50% aqueous ethanol, cooled in ice, and basified under ether with ammonia. The ether extract was set aside overnight, and the crystalline matter that separated during that time was collected, washed with methanol, and recrystallized from 2-ethoxyethanol, when 8,14-dihydro-6,7 $\alpha$ -epoxy-5'-methyl-5'-phenylcyclopentano[1',2':8,14]deoxycodine-D (XXXVIII) was obtained as white prisms, mp 234° (0.3 g).

*Anal.* Calcd for  $C_{28}H_{34}NO_2$ : C, 78.3; H, 7.2. Found: C, 78.2; H, 7.2.

The ether solution after removal of this base was evaporated to leave a brown viscous gum, part of which was chromatographed

in ether solution on alumina plates. From the plates a nonphenolic  $\alpha,\beta$ -unsaturated ketone XIII ( $R = Me$ ,  $R' = Ph$ ), a nonphenolic saturated ketone, and a nonphenolic aldehyde were obtained as well as a phenolic saturated ketone. Chromatographic separation of a further part of the same viscous gum on silica plates resulted in the separation of the material into a nonphenolic fraction and six nonphenolic bases which on recovery from the plate showed almost identical infrared absorption lacking any band attributable to a carbonyl group. The amounts of material recovered in this way were too small to permit further study.

**Abstract:** The acid-catalyzed rearrangement of alcohols of the 6,14-*endo*-ethenotetrahydrothebaine series of general structure I has been shown to proceed in most cases *via* the 14-alkenylcodeinones (II) to 7,8-dihydrocyclohex-4'-*eno*- and -cyclohex-5'-*eno*[1',2':8,14]codeinones of general structures X and XI. The structures of typical bases have been elucidated by nmr spectral studies and by chemical means. Analogous derivatives of dihydromorphinone and a series of nor bases and N-substituted nor bases have also been prepared. The mechanisms of the rearrangements are discussed.

In the preceding paper it is shown that the alcohols of general structure I can be rearranged to 14-alkenylcodeinones (II), which may be further transformed by concentrated hydrochloric acid into 5,14-bridged thebainone derivatives III. The last of these transformations, however, competes with an alternative process, which in general represents the major reaction, the thebainone derivative III being the major product only in special cases. The alternative rearrangement of the codeinone II affords a nonphenolic nonconjugated ketone as the stable end product, which is, of course, obtained also by the complete rearrangement of the alcohol I under the same conditions, and from the olefin which is an intermediate in the conversion of the alcohol into the codeinone II (see preceding paper). As would be expected, since carbonium ion intermediates are clearly involved in the dehydration and rearrangement of the alcohol I to the codeinone II, di-

astereoisomeric pairs of alcohols afford the same ketonic end product, in all cases studied. The rearrangement of the alcohol I ( $R = H$ ,  $R' = Ph$ ) is a particularly rapid process; in cold concentrated hydrochloric acid the product is almost entirely the codeinone II ( $R = H$ ,  $R' = Ph$ ), and this is completely converted into stable end products after only 4-min boiling. The nonphenolic nonconjugated ketones obtained in this way are isomeric with the alkenylcodeinones II and the thebainone derivatives III prepared from the same alcohols.

One possible process by which the alkenylcodeinone II could be converted into a nonconjugated ketone involves the protonation of the enone system and non-Markovnikov addition of the resulting carbonium ion to the double bond in the side chain, followed by expulsion of a proton to give the ketone VI. However, the codeinone II ( $R = H$ ,  $R' = Me$ ) is known to suffer recyclization in acid solution, by a process involving Markovnikov addition to the isolated double bond, to give the alcohol V ( $R = H$ ,  $R' = Me$ ),<sup>1</sup> and the rearrangement of such a cyclized base to the noncon-

jugated ketone IV by the successive 1,2 shifts shown in formula V is also a plausible process, several variants of which can be envisaged.

The nmr spectra of three of these ketones, obtained by the acid-catalyzed rearrangement of the tertiary alcohols I ( $R = H$ ,  $R' = Ph$ ;  $R' = Me$ ,  $R = Me$ ; and  $R' = Me$ ,  $R = i-Bu$ ), however, showed no evidence of the presence in these three bases of the system  $CH=CH$ , signals due to which are clearly observed in the spectra of the parent alcohols I and the alkenyl-codeinone II ( $R = H$ ,  $R' = Ph$ ). Indeed only in the spectrum of the first of these ketones (from the alcohol I,  $R = H$ ,  $R' = Ph$ ) is the presence of even a single olefinic proton indicated. Further the spectrum of the first of these ketones shows no signal attributable to a C-methyl group, and the spectrum of the second ketone (from the alcohol I,  $R' = Me$ ,  $R = Me$ ) shows C-methyl signals only at  $\delta$  1.53 and 1.61, which evidently arise from groups in the system  $C=CCH_3$ . The spectrum of the third ketone (from the alcohol I,  $R' = Me$ ,  $R = i-Bu$ ) also shows a three-proton singlet at  $\delta$  1.62 ( $C=CCH_3$ ) as well as a complex signal centered at  $\delta$  0.81, attributed to the system  $CHMe_2$ .

The spectra of all three ketones show signals attributable to two aromatic protons at C-1 and C-2, at about  $\delta$  6.68, and in addition the first of the three shows a five-proton complex signal at about  $\delta$  7.33 clearly due to the phenyl group. All three ketones show a one-proton singlet at  $\delta$  4.5–4.55, which is attributed to the proton at C-5 at the end of the cyclic ether bridge.

These spectra rule out of consideration the structures IV and VI for the three above-mentioned ketones, but do lead to the assignment of plausible structures to these and analogous compounds on the basis of a rational reaction mechanism for the acid-catalyzed rearrangements. The 14-alkenylcodeinone (II), which may be redrawn as VII, may very reasonably be expected to be in prototropic equilibrium in acid solution with the isomeric alkenylcodeinone VIII, which can then suffer protonation of the enone system and Markovnikov addition of the resulting carbonium ion to the double bond in the side chain to give the

carbonium ion IX, which can lose a proton in either two ways to give the ketones X and XI. The examination of models suggests that a similar cyclization of codeinone VII to give IV, in addition to requiring a Markovnikov addition to the double bond, is inhibited by the impossibility of arranging the double bond a position relative to the enone system suitable for cyclization. The examination of models of the isomeric system VIII, however, shows that in this double bond in the side chain can readily be positioned over C-8 in precisely the geometry required for p

pendicular attack of the enone system in the manner favored for Michael addition<sup>3</sup> and the conjugated addition of Grignard reagents.<sup>4</sup> Such a process would result in the formation from the alcohol I ( $R' = \text{Me}$ ,  $R = \text{Me}$ ) of the ketone X ( $R = R' = \text{Me}$ ) which contains the system  $\text{CH}_2\text{C}=\text{CCH}_3$  and no olefinic proton, and from the alcohol I ( $R' = \text{Me}$ ,  $R = i\text{-Bu}$ ) of the ketone X ( $R' = \text{Me}$ ,  $R = i\text{-Bu}$ ). In these cases hyperconjugation effects may be presumed to favor the formation of the olefin X rather than the isomeric olefin XI.

The application of this reaction mechanism to the rearrangement of the alcohol I ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) would lead through the codeinones VII ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) and VIII ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) to the ketones X ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) or XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) or both. Both of these ketones are formulated with styrenoid chromophores, and indeed the product of the rearrangement does show styrenoid ultraviolet absorption. This rearrangement product has been separated into two isomeric ketones, the infrared and ultraviolet spectra of which are closely similar, and these can be formulated as the two isomers X ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) and XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ). The nmr spectra of both isomers showed complex patterns for one olefinic proton, which made a distinction between structures X and XI very difficult without additional information. The identification of one isomer was possible, however, using spin-decoupling techniques. The spectrum of one of these ketones (mp 161–163°) (Figure 1) showed an olefinic proton as a multiplet (1 H) at about  $\delta$  6.1. Irradiation at about  $\delta$  2.1 collapsed this  $\delta$  6.1 multiplet into a doublet ( $J \cong 7$  cps), indicating further coupling with another proton. That this proton is one absorbing at about  $\delta$  3.8 was shown by irradiation at this point, when the olefinic proton signal then appeared as a broad single peak. The proton pattern at  $\delta$  3.8 is a quartet, which collapsed to a doublet ( $J = 18$  cps) when the olefinic proton was irradiated. The proton absorbing at  $\delta$  3.8 was also coupled with the one absorbing at about  $\delta$  2.1 ( $J = 18$  cps), as shown by irradiation at about  $\delta$  2.1. The  $J = 18$  cps can only be a *gem*-coupling constant. The proton giving the quartet at  $\delta$  3.8 must, therefore, be one-half of a methylene group adjacent to an olefinic proton.

Since the double bond is presumably the one present in the styrenoid system this ketone evidently contains the system  $\text{CH}_2\text{CH}=\text{CPh}$ , which is that present in the base XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ). The downfield shift of one of the methylene protons in this system to  $\delta$  3.8 is regarded as resulting from this proton being both allylic and near the unshared pair of electrons on the nitrogen atom<sup>5,6</sup> as it is in a model of the ketone XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ). The other proton in this methylene group resonates at  $\delta$  2.17. Such large differences between halves of a methylene group are unusual, but not unprecedented.<sup>7</sup>

Figure 1. Nmr spectrum of 7,8-dihydro-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone (XI,  $R = \text{H}$ ,  $R' = \text{Ph}$ ). Arrows show spin system established by decoupling experiments.

It is clear, therefore, that the nmr spectrum of this ketone (mp 161–163°) is entirely consistent with the structure XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ). The isomeric ketone (mp 212–214°), which is the minor product of the acid-catalyzed rearrangement of the alcohol I ( $R = \text{H}$ ,  $R' = \text{Ph}$ ), gave an nmr spectrum substantially similar to that of the ketone (mp 161–163°). In this case, however, the complex olefinic proton signal at about  $\delta$  6.0 collapsed and appeared as a single peak, still showing residual coupling, on irradiation at about  $\delta$  2.4, thus establishing that the olefinic proton is coupled to a proton or protons absorbing at the latter point. Owing to the coincidence of other resonances in the  $\delta$  2.4 region, however, it was not possible to observe clear-cut changes in the spin-spin decoupling studies. Since this ketone is styrenoid and isomeric with one whose spectrum is consistent with the structure XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) it may with confidence be assigned the structure X ( $R = \text{H}$ ,  $R' = \text{Ph}$ ). If these structural assignments are correct the two ketones represent the products of alternative modes of the loss of a proton from the carbonium ion IX ( $R = \text{H}$ ,  $R' = \text{Ph}$ ), through which they may be equilibrated in acid solution. This equilibration has been independently achieved, for each of the two pure ketones on treatment with *p*-toluenesulfonic acid in glacial acetic acid<sup>8</sup> is converted into a mixture of approximately 80% of the ketone XI ( $R = \text{H}$ ,  $R' = \text{Ph}$ ) and 20% of the isomer X ( $R = \text{H}$ ,  $R' = \text{Ph}$ ), which is the composition of the crude product obtained in the rearrangement of the alcohol I ( $R = \text{H}$ ,  $R' = \text{Ph}$ ).

Although the spectra of the ketones discussed above are compatible with one or other of the structures X or XI for these bases, they do not provide any definitive information pertaining to the structure of the carbonyl-containing ring C, and, accordingly, chemical transformations have been carried out on two of these bases

(8) These conditions have been used for the equilibration of *cis*- and *trans*-2-phenyl-2-butene: D. J. Cram and M. V. R. Sahyun, *J. Am. Chem. Soc.*, **85**, 1257 (1963).

(7) For example, one of the benzylic methylene protons, shielded by the phenyl moiety in **i**, appears at  $\delta$  3.67 while the other methylene proton, deshielded by the carbonyl group, resonates at  $\delta$  5.42: A. H. Lewin, J. Lipowitz, and T. Cohen, *Tetrahedron Letters*, 1241 (1965).

to characterise this portion of the molecule. That the ketones still contain the 4,5-oxygen bridge intact may be inferred from their nonphenolic nature, and from the presence in their nmr spectra of the sharp singlet at about  $\delta$  4.5 attributed to the C-5 proton. The presence of the oxygen bridge and the relationship of this to the carbonyl group in the ketones are demonstrated by the behavior of two of the ketones on Huang-Minlon reduction. The reduction of derivatives of dihydrocodeinone by this process occurs with great ease, and involves fission of the 4,5-oxygen bridge and the production of derivatives of the phenolic dihydrodeoxycodines B and C.<sup>9</sup> The hydrazones of the ketones XI ( $R = H$ ,  $R' = Ph$ ) and X ( $R = i-Bu$ ,  $R' = Me$ ) lose nitrogen at about  $120^\circ$  in alkaline solution and give phenolic products, which give positive tests with Gibb's reagent (dichloroquinone chlorimine) and with diazotized sulfanilic acid. The major product of reduction of the base X ( $R = i-Bu$ ,  $R' = Me$ ) shows nmr signals as doublets at  $\delta$  6.3 and 5.5 ( $CH=CH$ ,  $J_{A,B} = 9$  cps) and a singlet at  $\delta$  5.87 shifted to  $\delta$  7.95 in dimethyl sulfoxide, attributed to the phenolic hydroxyl proton. On mechanistic grounds this major product of the reaction is assigned the formula XII and the minor product may be the analogous derivative of dihydrodeoxycodine-C with a 6,7-double bond. This reaction can only be represented by a satisfactory mechanism if the carbonyl group in the ketones is located at C-6.

The ketones X ( $R = i-Bu$ ,  $R' = Me$ ) and XI ( $R = H$ ,  $R' = Ph$ ) are converted into enol acetates on heating with acetic anhydride and sodium acetate, and the enol esters are readily hydrolyzed to the parent ketones by hot hydrochloric acid. The examination of models shows that if the carbonyl group is contained in a five-, six-, or seven-membered ring enolization cannot involve the hydrogen atom at C-5 since the introduction of a 5,6 double bond would impose an unacceptable degree of strain on the oxygen-containing ring. Enolization must, therefore, involve C-7, and the nmr spectrum of the enol acetate XIII supports the assigned structure, showing signals (in  $\delta$  units) at 6.7 (two aromatic H), 5.38 doublet (C-7,  $J_{7,5} = 2$  cps), 4.91 doublet (C-5 H,  $J_{5,7} = 2$  cps), 3.88 (aromatic  $OCH_3$ ), 2.33 ( $NCH_3$ ), 2.16 ( $COCH_3$ ), 1.62 ( $C=CCH_3$ ), and a complex six-proton peak at 0.82 ( $CHMe_2$ ). C-Methylation

of the ketone X ( $R = i-Bu$ ,  $R' = Me$ ) can be accomplished with potassium *t*-butoxide and methyl iodide, and the nmr spectrum of the product XIV ( $R = Me_2$ ) is very similar to that of the starting material except in the region  $\delta$  0.6–1.2 in which signals are found integrating for a total of 12 protons, indicating that two new methyl groups have been introduced at C-7. The dimethylated ketone, which bears no enolizable hydrogen atom, is recovered unchanged after heating with sodium acetate and acetic anhydride. These reactions clearly show that the parent ketones contain the system  $OCHCOCH_2$  as in formulas X and XI.

The presence of this system in the ketone X ( $R = i-Bu$ ,  $R' = Me$ ) was confirmed by the conversion of the base into an  $\alpha$ -oximino ketone XIV ( $R = NOH$ ) by the action of sodium ethoxide and amyl nitrite. The base obtained in this way was soluble in alkalis and was precipitated from the solution by ammonium chloride or carbon dioxide. It also gave an insoluble stable copper chelate with methanolic cupric acetate, which was soluble in dilute acids and reprecipitated unchanged by ammonia. The  $\alpha$ -oximino ketone was hydrolyzed by hot dilute sulfuric acid to a yellow  $\alpha$ -diketone XIV ( $R = O$ ), which gave a dark brown cupric complex and with ferric chloride gave a deep wine red solution that became intensely blue-green on the addition of a trace of ammonia. From this it may be concluded that the diketone is enolizable, and hence must contain the system  $OCHCOCOCH$ , which means that the original ketone X ( $R = i-Bu$ ,  $R' = Me$ ) must contain the system  $OCHCOCH_2CH$ . Further evidence for the presence of this system in the same ketone was obtained from the action on it of bromine and potassium carbonate in methanol, in an attempt to prepare the diketone XIV ( $R = O$ ) by the method used in the dihydrocodeinone and sinomenine series.<sup>10</sup> The reaction afforded a mixture of products from which a small quantity of an  $\alpha,\beta$ -unsaturated ketone was isolated. Presumably this is formed from the  $\alpha$ -bromo ketone by the loss of hydrogen bromide.

The chemical evidence given above indicates the nature of most of ring C in the rearranged bases, and, if the reasonable assumption is made that the dihydrocodeinone ring system remains intact, the complete structures of these bases must be made up by the addition of a new ring, which can only be added at positions 8 and 14. This new ring can only be five or six membered and must contain a double bond to satisfy the compositions of the bases, and the nmr spectra of the bases examined are only compatible with the arrangement of this ring as shown in formulas X and XI. The complete structures based on these general formulas can, therefore, be confidently assigned to the rearranged bases.

The position of the double bond in the end products of the rearrangement is determined by the nature of the substituents in the unsaturated ring. The major product of the rearrangement of the alcohol I ( $R = H$ ,  $R' = Ph$ ) is the ketone XI ( $R = H$ ,  $R' = Ph$ ), though some of the isomeric ketone X ( $R = H$ ,  $R' = Ph$ ) is also formed. The cyclohexenocodine obtained in the rearrangement of the alcohol I ( $R = H$ ,  $R' = Me$ ) has also been identified as the  $\Delta^4$  ketone XI ( $R = H$ ,  $R' = Me$ ) [nmr signals (in  $\delta$  units) at 6.64

<sup>a</sup> Δ' isomer.

Established reactions are indicated by solid arrows, and hypothetical reactions (which appear to be allowable by rational mechanistic considerations) are shown by dotted arrows.

The distribution of products formed depends on the reaction conditions (*i.e.*, the strength and concentration of acid and time of heating) and the substituents R and R'. For example, the transformations described in the upper two-thirds of Scheme I (XVII-XXII) are generally achieved with dilute hydrochloric acid at 25 to 50°, with 99% formic acid at 100°, or with perchloric acid in trimethyl orthoformate, methanol, and methylene chloride at 25°. Transformations of bases of structure XXII into those of structures XXIII and XXV, however, have required 6-12 *N* hydrochloric acid at 100°. The influence of substituents on the distribution

of final products is illustrated by the conversion of the base XVII (R' = Ph, R = H) into a mixture containing 95% of the base XXIII (R' = Ph, R = H; as the isomeric olefins) and 5% of the phenol XXV (R' = Ph, R = H), while treatment of the base XVII (R' = Me, R = H) under similar conditions gave 35% of the phenol XXV (R' = Me, R = H) and 36% of the ketone XXIII (isolated yields). Nepenthen (XII, R' = Ph, RCH<sub>2</sub> = H) is, of course, incapable of isomerism to an olefin of structure XXIV and, therefore, yields flavone-penthen (XXV, R' = Ph, RCH<sub>2</sub> = H). The observed recyclization reactions of the 14-alkenyl derivative XXII or XXIV (XXII → XXI → XIX, XXII → XXV, XXIV → XXIII) represent Markovnikov additions of an electrophilic center at C-5, C-6, or C-8 to the double bond, producing a five- or six-membered

ring. Products formed by anti-Markovnikov additions of these electrophilic centers or by Markovnikov additions to form four- or seven-membered rings have not been found. Similarly, products formed by 1,2 migration of the 7,8 or 6,7 bonds or by 1,3 migration of the 6,18 bond to the *t*-carbonium ion C-19 in XXI have not been observed.

## Experimental Section

**Rearrangement of 6,14-endo-Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-phenylethyl)tetrahydrothebaine (19-Phenylthevinol, I, R' = Me, CH<sub>2</sub>R = Ph).** 6,14-endo-Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-phenylethyl)tetrahydrothebaine (5 g) was heated with concentrated hydrochloric acid (100 ml) and ethanol (15 ml) on the steam bath for 30 min during which time a sparingly soluble salt separated. This was collected, washed with cold water, and dissolved in hot 50% aqueous ethanol. The resulting solution was basified with ammonia, and the precipitated solid was collected and recrystallized from ethanol, when it was obtained as almost colorless plates, mp 149–151°,  $\nu_{\max}$  1730 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>3</sub>: C, 78.6; H, 6.8. Found: C, 78.6; H, 7.8.

The same material was obtained when 6,14-endo-etheno-7 $\alpha$ -(1-(*S*)-hydroxy-1-phenylethyl)tetrahydrothebaine or 14-(3-phenylbut-2-enyl)codeinone (II, R = Me, R' = Ph) was rearranged in the same way with hot concentrated hydrochloric acid. Thin layer chromatographic studies showed this base to be a mixture of three components.

The base (0.363 g) was chromatographed on a column of Merck acid-washed alumina (60 g) and the chromatogram was developed with 200 ml of 1% ethyl acetate in benzene. Elution of the column with 2% (200 ml) and 5% (600 ml) ethyl acetate in benzene gave 29–20-mL fractions, each of which was examined by thin layer chromatography on alumina. Similar fractions were combined and concentrated. The first component eluted from the column (0.023 g) was 14-(3-phenylbut-2-enyl)codeinone (II, R = Me, R' = Ph) identical in infrared absorption and behavior on thin layer plates with an authentic specimen. The second component (0.204 g) was 7,8-dihydro-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone (XI, R = H, R' = Ph), mp 161–163° after two recrystallizations from methanol,  $\nu_{\max}$  1730 cm<sup>-1</sup>,  $\lambda_{\max}$  241 m $\mu$  ( $\lambda_{\max}$  248 m $\mu$  ( $\epsilon_{\max}$  13,400) after subtraction of the benzenoid absorption of the base I, R = H, R' = Me).

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>3</sub>: C, 78.6; H, 6.8. Found: C, 78.3; H, 6.8.

The third component (0.020 g) was 7,8-dihydro-5'-phenylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = H, R' = Ph), mp 208–210°, raised to 212–214° when separated from a small amount of the  $\Delta''$  isomer on five 0.3-mm thick 20 × 20 cm alumina plates,  $\nu_{\max}$  1730 cm<sup>-1</sup>,  $\lambda_{\max}$  241 m $\mu$  ( $\lambda_{\max}$  252 m $\mu$  ( $\epsilon_{\max}$  12,200) after subtraction of the benzenoid absorption of the base I, R = H, R' = Me).

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>3</sub>: C, 78.6; H, 6.8. Found: C, 78.6; H, 6.8.

**Equilibration of the Isomeric Olefins X (R = H, R' = Ph) and XI (R = H, R' = Ph).** Solutions containing 2.5 mg each of 7,8-dihydro-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone (XI, R = H, R' = Ph) and 7,8-dihydro-5'-phenylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = H, R' = Ph) (the latter containing 16% of the  $\Delta''$  isomer) in 0.10 ml of benzene were prepared. Each solution, after the withdrawal of 0.02 ml for standardization, was treated with 0.47 ml of 0.1 *M* *p*-toluenesulfonic acid in glacial acetic acid to make the solutions about 0.01 *M* in olefin and 0.09 *M* in toluenesulfonic acid. These solutions were heated at 95–100° and, after designated intervals, 0.14-ml aliquots were removed and added to a mixture of 0.2 ml of concentrated ammonium hydroxide and four drops of benzene. These mixtures were agitated and centrifuged, and the benzene layer was spotted along the bottom edge of a 5 × 20 cm silica gel G plate and developed with 2% triethylamine in benzene (occasionally redeveloped several times to obtain a satisfactory separation). The separated isomers were located with the aid of an ultraviolet lamp (250 m $\mu$ ) and the respective zones were removed from the plates, extracted with methanol, and diluted to a known volume (5.0 to 25.0 ml, according to the size of the sample). The absorbances at 250 m $\mu$  were then measured for each solution, and the percentage composition of each aliquot removed from the reaction mixture was then calculated using the known  $\epsilon_{250\text{m}\mu}^{\text{MeOH}}$  for the pure isomers. The results obtained are set out in Table II.

Table II

Time, hr	% Composition of mixture A		% Composition of mixture B	
	X	XI	X	XI
0	0	100	84	16
1	8	92	63	37
2	12	88	42	58
20	18	82	19	81

**7,8-Dihydro-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone (XI, R = H, R' = Ph, CO = CHO).** The mixture of isomers XI (R = H, R' = Ph) and X (R = H, R' = Ph) (5 g) obtained from the rearrangement of 6,14-endo-etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-phenylethyl)tetrahydrothebaine (I, R' = Me, CH<sub>2</sub>R = Ph) was reduced with sodium borohydride (0.5 g) in hot ethanol (200 ml). The resulting alcohol was precipitated from solution by the addition of water, collected (5 g), and recrystallized four times from ethanol, when it was obtained as white prisms, mp 191°, giving only one spot on thin layer chromatograms.

*Anal.* Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>3</sub>: C, 78.4; H, 7.3. Found: C, 78.1; H, 7.4.

**7,8-Dihydro-6'-methyl-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone (XI, R = Me, R' = Ph).** 6,14-endo-Etheno-7 $\alpha$ -(1-(*S*)-hydroxy-1-phenylpropyl)tetrahydrothebaine (I, R' = Ph, R = Me) (2 g) was heated in the water bath for 1 hr with concentrated hydrochloric acid (50 ml). The mixture was diluted with water when a viscous hydrochloride separated. This was dissolved by the addition of ethanol, and the aqueous alcoholic solution was basified with ammonia. The precipitated noncrystalline base was collected, washed with water, and crystallized from 2-ethoxyethanol. On recrystallization from this solvent 7,8-dihydro-6'-methyl-5'-phenylcyclohex-4'-eno[1',2':8,14]codeinone was obtained as pale cream prisms, mp 224–226°, showing one spot only on thin layer chromatograms,  $\nu_{\max}$  1730 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>25</sub>H<sub>31</sub>NO<sub>3</sub>: C, 78.8; H, 7.0. Found: C, 78.6; H, 6.9.

The same base was obtained by the rearrangement of 14-(3-phenylpent-2-enyl)codeinone (II, R = Me, R' = Ph) in concentrated hydrochloric acid.

**7,8-Dihydro-5'-methylcyclohex-4'-eno[1',2':8,14]codeinone (XI, R = H, R' = Me).** 6,14-endo-Etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (I, R = H, R' = Me) (0.50 g) was heated in hydrochloric acid (2 ml, *d* 1.19) on the steam bath for 90 min, during which time crystals separated. Water (2 ml) was added, and the solid matter was collected, when 5,14-ethano-18-isopropylidenethebaine hydrochloride (III, R = H, R' = Me) (0.175 g), mp 310–315°, was obtained (see part IV of this series).

The combined filtrate and washings from the collection of this hydrochloride were neutralized with aqueous sodium bicarbonate and the resulting base was isolated by extraction with methylene chloride. The glass remaining after removal of the solvent was dissolved in methylene chloride and chromatographed on alumina (Woelm, activity II, 20 g). Continued elution of the column with methylene chloride afforded material that was crystallized from *n*-hexane, when 7,8-dihydro-5-methylcyclohex-4'-eno[1',2':8,14]codeinone (165 mg) was obtained as prisms, mp 112–114°,  $\nu_{\max}$  1725 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>23</sub>H<sub>27</sub>NO<sub>3</sub>: C, 75.6; H, 7.45. Found: C, 76.0; H, 7.4.

**7,8-Dihydro-5',6'-dimethylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = R' = Me).** 6,14-endo-Etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-methylpropyl)tetrahydrothebaine (I, R' = Me, R = Me) (5 g) was heated on the steam bath for 1 hr with concentrated hydrochloric acid (25 ml). The mixture was diluted with aqueous ethanol and made alkaline with ammonia. The resulting base was collected and recrystallized from ethanol, when it was obtained as white prisms, mp 199°,  $\nu_{\max}$  1730 cm<sup>-1</sup>.

*Anal.* Calcd for C<sub>24</sub>H<sub>31</sub>NO<sub>3</sub>: C, 76.0; H, 7.6. Found: C, 76.1; H, 7.9.

The same base was obtained by the rearrangement of 6,14-endo-etheno-7 $\alpha$ -(1-(*S*)-hydroxy-1-methylpropyl)tetrahydrothebaine (I, R' = Et, R = H) in the same way.

**7,8-Dihydro-5'-ethyl-6'-methylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = Me, R' = Et).** This base was obtained as above by heating 6,14-endo-etheno-7 $\alpha$ -(1-hydroxy-1-ethylpropyl)tetrahydrothebaine (1 g) with concentrated hydrochloric acid (5 ml) on the steam bath for 1 hr. It formed prisms, mp 198°, from ethanol,  $\nu_{\max}$  1730 cm<sup>-1</sup>.

from methanol, when the phenolic base XII was obtained (0.55 g) as white felted needles, mp 127–129°.

*Anal.* Calcd for  $C_{27}H_{37}NO_2$ : C, 79.5; H, 9.1. Found: C, 79.1; H, 9.3.

The infrared spectrum showed no carbonyl absorption, and the nmr spectrum showed signals (in  $\delta$  units) at 6.61 (two aromatic H), 6.3 and 5.5 (doublets,  $J_{AB} = 9$  cps,  $CH=CH$ ), 5.85 (OH), 3.85 ( $OCH_3$ ), 2.3 ( $NCH_3$ ), 1.58 ( $C=CCH_3$ ), and 0.80 (complex,  $CHMe_2$ ). The signal due to the hydroxyl proton was moved to  $\delta$  7.93 in dimethyl sulfoxide.

The base was not readily soluble in aqueous alkalis but in ethanolic potassium hydroxide it coupled readily with diazotized sulfanilic acid to give a blood red solution.

The picrate was obtained as canary yellow needles, mp 186° from ethanol.

*Anal.* Calcd for  $C_{27}H_{37}NO_2 \cdot C_6H_5N_2O_7$ : C, 62.2; H, 6.3; N, 8.8. Found: C, 61.9; H, 6.5; N, 9.2.

The methanolic mother liquors from the recrystallization of the original reaction product on evaporation afforded a gum from which a second picrate (0.200 g) was obtained as dark yellow prisms, mp 190°.

*Anal.* Calcd for  $C_{27}H_{37}NO_2 \cdot C_6H_5N_2O_7$ : C, 62.2; H, 6.3; N, 8.8. Found: C, 61.9; H, 6.5; N, 9.1.

This is believed to be the picrate of the  $\Delta^4$  isomer of the base XII since the base recovered from the salt still gave a blood red color with diazotized sulfanilic acid in alcoholic potassium hydroxide solution.

**6-Acetoxy-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]-deoxycodine-C (XIII).** 7,8-Dihydro-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = *i*-Bu, R' = Me) (1.5 g), acetic anhydride (7.5 ml), and anhydrous sodium acetate (0.25 g) were boiled together under reflux for 1.75 hr. The mixture was poured into water and the base was liberated with sodium carbonate and extracted with ether. The extracts yielded an orange gum that crystallized on standing. Recrystallization from methanol afforded the enol acetate (1.0 g) as white needles, mp 132°,  $\nu_{max}$  1750  $cm^{-1}$ .

*Anal.* Calcd for  $C_{29}H_{39}NO_4$ : C, 75.2; H, 8.0. Found: C, 75.5; H, 8.2.

This enol acetate was heated with aqueous ethanolic hydrochloric acid on the water bath for 30 min, and the mixture was neutralized with ammonia to give 7,8-dihydro-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = *i*-Bu, R' = Me), mp 196° alone or mixed with an authentic specimen,  $\nu_{max}$  1730  $cm^{-1}$ .

**7,8-Dihydro-6'-isobutyl-8,8,5'-trimethylcyclohex-5'-eno[1',2':8,14]codeinone (XIV, R = Me).** A suspension of 7,8-dihydro-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = *i*-Bu, R' = Me) (1 g) in dry *t*-butyl alcohol (10 ml) was added to a solution of potassium (0.5 g) in dry *t*-butyl alcohol (75 ml) and the mixture stirred for 10 min at 30°. Excess of methyl iodide (2 ml) was then added, and the mixture was stirred for 1 hr after which it was poured into water. The product was isolated by ether extraction and recrystallized from methanol when 7,8-dihydro-6'-isobutyl-8,8,5'-trimethylcyclohex-5'-eno[1',2':8,14]codeinone (0.4 g) was obtained as white plates, mp 169–170°,  $\nu_{max}$  1710  $cm^{-1}$ .

*Anal.* Calcd for  $C_{29}H_{39}NO_2$ : C, 77.5; H, 8.75. Found: C, 77.2; H, 8.8.

The nmr spectrum was identical with that of the starting material except in the region  $\delta$  0.6–1.2 in which region signals integrate for 12 protons instead of 6. The base was recovered unchanged

after heating under reflux for 2 hr with acetic anhydride and anhydrous sodium acetate.

**7,8-Dihydro-7-hydroxyimino-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (XIV, R = NOH).** A solution of sodium (0.25 g) in ethanol (10 ml) was added to a suspension of 7,8-dihydro-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (X, R = *i*-Bu, R' = Me) (1 g) in ethanol (20 ml) and the mixture heated on the water bath for 5 min, then cooled to 60°. Isoamyl nitrite (0.4 g) in ethanol (1.5 ml) was then added and the resulting mixture, which rapidly became dark brown, set aside until a test portion gave only a slightly turbid solution when poured into excess of aqueous sodium hydroxide (about 15 min). The mixture was then poured into aqueous 2 *N* sodium hydroxide solution (50 ml) and insoluble matter was removed by ether extraction. The base was precipitated from the aqueous layer by the addition of ammonium chloride solution, collected, washed with water, and recrystallized from methanol, when the isonitroso ketone (0.8 g) was obtained as white prisms, mp 238–240°,  $\nu_{max}$  1700  $cm^{-1}$ .

*Anal.* Calcd for  $C_{28}H_{34}N_2O_4$ : C, 72.0; H, 7.55. Found: C, 71.7; H, 7.5.

The base gave an immediate green-brown precipitate on treatment in methanol solution with methanolic cupric acetate. The precipitate dissolved readily to give an almost colorless solution in acids but was recovered unchanged on the addition of ammonia, no cupric tetraammine salt being obtained.

**7,8-Dihydro-6'-isobutyl-5'-methyl-7-oxocyclohex-5'-eno[1',2':8,14]codeinone (XIV, R = O).** A solution of 7,8-dihydro-7-hydroxyimino-6'-isobutyl-5'-methylcyclohex-5'-eno[1',2':8,14]codeinone (XIV, R = NOH) (0.5 g) in 2 *N* sulfuric acid (10 ml) was heated at 100° for 30 min, then basified with ammonia. The precipitated base was isolated by ether extraction and dissolved in hot petroleum ether (bp 60–80°). On cooling the solution deposited a green amorphous solid, which in petroleum ether suspension slowly became crystalline. The crystalline solid was collected, washed free of amorphous material with cold benzene, and recrystallized from benzene, when the  $\alpha$ -diketone XIV (R = O) (0.28 g) was obtained as canary yellow prisms, mp 198–200°.

*Anal.* Calcd for  $C_{27}H_{33}NO_4$ : C, 74.5; H, 7.6. Found: C, 74.6; H, 7.8.

The base gave a deep wine red color with ethanolic ferric chloride, which became an intense blue green on the addition of a trace of ammonia.

The hydrochloride, prepared in ethanol and recrystallized from 2-ethoxyethanol containing 10% water, was obtained as light yellow prisms, mp 215–217°.

*Anal.* Calcd for  $C_{27}H_{33}NO_4 \cdot HCl \cdot 1.5H_2O$ : C, 64.8; H, 7.4. Found: C, 64.8; H, 7.6.

*Contribution from the Research Laboratories, Reckitt and Sons Ltd., Kingston-upon-Hull, England. Received September 26, 1966*

**Abstract:** The 7 $\alpha$  and 7 $\beta$  ketones of the 6,14-*endo*-etheno- and -ethanotetrahydrothebaine series I suffer base-catalyzed rearrangement to isomeric bases VIII, though the reaction may be interrupted by other reagents at an intermediate stage II or V. The rearrangement of the esters and nitriles of this series does not proceed beyond the stage X or XII, corresponding to V. All of these products are unstable to acids which readily convert them into derivatives of 5,14-ethanothebainone III, VI, VII, and XII. The catalytic reduction of and the reaction of organometallic compounds with the ketone VIII have been studied. 18-Acetyl-5,14-ethanothebainone (VII, R' = H) has been shown to undergo base-catalyzed ketolization to the hexacyclic base XXV. The Hofmann degradation of the quaternary salts of certain of the rearranged bases has been shown to proceed normally.

The ketone nepenthone (I, CH<sub>3</sub> = Ph), which is the Diels–Alder adduct of thebaine and phenyl vinyl ketone, readily suffers base-catalyzed rearrangement to isonepenthone (VIII, CH<sub>3</sub> = Ph),<sup>2</sup> and similar rearrangements have been effected with certain other adducts of thebaine bearing electron-withdrawing substituents at C-7. The aldehyde I (CH<sub>3</sub> = H), the ketone I,<sup>2,3</sup> the ester I (CH<sub>3</sub> = OEt),<sup>3</sup> and the 7-nitrile I (COCH<sub>3</sub> = CN)<sup>2,3</sup> have all been subjected to base-catalyzed rearrangement as have some of their 6,14-ethano analogs. The reaction is initiated by the removal of the C-7 proton, which is  $\alpha$  to the activating group. Although the methyl ketone I is initially enolized by removal of a proton from the methyl group under kinetic control,<sup>3</sup> under reversible conditions removal of the C-7 proton occurs with formation of an enolate ion in which C-7 is no longer asymmetric and both 7 $\alpha$  and 7 $\beta$  forms of the reactive species give the same product after rearrangement.

Following the removal of the C-7 proton displacement of the 4,5-oxide bridge by the carbanion occurs to give the phenate ion IV, and the final fate of this ion then depends on the nature of C-7 substituent and on the conditions of the reaction. If no other reagent is present, and if the electron-accepting power of the C-7 substituent is great enough, *i.e.*, if this is a keto group, the cyclopropane ring may be opened under attack at C-5, which would lead to the starting material, or at C-6, which leads to the rearranged base VIII. The examination of models of the molecules of structures I and VIII shows that the ring system, and in particular the oxygen-containing ring, of the latter is appreciably the less strained of the two and, since the reactions are clearly reversible, excellent yields of the rearranged bases are obtained.

If methyl iodide is added to a solution in *t*-butyl alcohol of the phenate anion IV, obtainable from either of the ketones I and VIII, methylation occurs; the

cyclopropane ring is not affected, and the product is the base V (R' = Me). The rearrangement also occurs under the influence of Grignard reagents functioning as bases,<sup>4</sup> and this process competes with the normal attack of the carbonyl group in the reaction of the ketone I and its 7 $\beta$  epimer with these reagents. In this reaction the initially formed phenate anion IV reacts further with the Grignard reagent at the carbonyl group to give a tertiary alcohol, thus effectively blocking the route for opening of the cyclopropane ring; the product is the phenolic alcohol II (R' = H). This represents only a minor side reaction of the ketone I with Grignard reagents but frequently accounts for as much as 40% of the product of the reaction in the 6,14-ethano series.

Base-catalyzed rearrangements of the ester I (CH<sub>3</sub> = OEt) and the nitrile I (COCH<sub>3</sub> = CN) are also easily effected. The products of simple rearrangement are the ester X (R = Et, R' = H) and the nitrile XII (R' = H); the electron-accepting power of the C-7 substituent in these cases apparently is insufficient to effect the production of analogs of the ketone VIII. The ester I (CH<sub>3</sub> = OEt) reacts normally with methylmagnesium iodide to give a tertiary carbinol,<sup>4</sup> but with other Grignard reagents the main products are the rearranged ester X (R = Et, R' = H) and the symmetrical tertiary carbinol II (R' = H, Me = R) resulting from the reaction of this ester with the reagent. The nitrile I (COCH<sub>3</sub> = CN) affords the rearranged base in excellent yield with aliphatic Grignard reagents, though with aromatic reagents some of the product of "normal" attack of the C $\equiv$ N group is also obtained.<sup>3</sup> The addition of alkyl or acyl halides during the rearrangement results in alkylation or acylation of the phenate ion, the products being the ethers or esters X (R' = Me) and XII (R' = Me, Et, Ac). The base-catalyzed rearrangement of the ester I (CH<sub>3</sub> = OEt) can also be combined with ester exchange processes; the products are esters of structure X (R' = H).

The nmr spectra of representative bases of the various groups are entirely in accord with the assigned structures. The spectrum of isonepenthone (VIII, CH<sub>3</sub> =

(1) Part V: K. W. Bentley, D. G. Hardy, C. F. Howell, W. Fulmor, J. E. Lancaster, J. J. Brown, G. O. Morton, and R. A. Hardy, Jr., *J. Am. Chem. Soc.*, **89**, 3303 (1967).

(3) Part I: K. W. Bentley and D. G. Hardy, *J. Am. Chem. Soc.*, **89**, 3267 (1967).

(4) Part II: K. W. Bentley, D. G. Hardy, and B. Meek, *ibid.*, **89**, 3273 (1967).

shows signals (in  $\delta$  units) at 8.2–7.2 (complex, five matic H), 6.6 (two aromatic H), 6.0 (doublet, C-8  $J_{8,7} = 9$  cps), 5.15 (doublet, C-7 H,  $J_{7,8} = 9$  cps, each k a doublet,  $J_{7,5} = 2$  cps), 3.82 (C-3  $\text{OCH}_3$ ), 3.55 5  $\text{OCH}_3$ ), and 2.30 ( $\text{NCH}_3$ ). The spectrum of the one VIII is virtually identical with that of isonepene except that it lacks the complex signals at  $\delta$  7.2 due to the phenyl group, and it shows instead gnal at  $\delta$  2.22 due to  $\text{COCH}_3$ . The examination of iding models of these ketones shows that disposi- 1 of the C-5 and C-7 hydrogen atoms is such as to mit long-range coupling, the two protons and the

intervening carbon atom C-6 lying in the same plane, the system being similar to those in which coupling is observed in narwedine and Pummerer's ketone.<sup>5</sup> Neither spectrum shows a signal at *ca.*  $\delta$  4.5 which is a feature of the spectrum of the ketone I,<sup>6</sup> attributed to the C-5 hydrogen atom at the end of the 4,5-oxygen bridge.

The spectrum of the ester X ( $R = \text{Et}$ ,  $R' = \text{H}$ ) in deuteriochloroform containing perdeuteriopyridine<sup>7</sup> showed signals due to the C-17 and C-18 protons (equivalent to C-8 and C-7 in VIII) at  $\delta$  5.93 and 5.72 (doublets,  $J_{17,18} = 9.0$  cps) showing no additional coupling. The C-5 hydrogen gave a signal at  $\delta$  3.57 as a single peak showing no coupling. The examination of models of the structure X shows that the dispositions of the C-5 and C-18 protons no longer meet the requirement for long-range coupling. The C-8  $\alpha\text{H}$  pattern was found as a doublet, coupling occurring only with C-8  $\beta\text{H}$  ( $J_{8\alpha,8\beta} = 13.0$  cps) indicating the absence of a hydrogen atom at C-7. The phenolic hydroxyl proton was signalled at *ca.*  $\delta$  8.0 in the presence of deuteriopyridine, but in the absence of this agent the signal appeared partially superimposed upon one line of the C-17 proton doublet at  $\delta$  5.82. The other fea-

(7) We are indebted to W. Fulmor, J. E. Lancaster, and G. O. Morton of Lederle Laboratories, Pearl River, N. Y., for the determination and interpretation of this spectrum.

tures of the spectrum of this ester were entirely consistent with the structure X ( $R = Et$ ,  $R' = H$ ).

The spectrum of the nitrile XII ( $R = H$ ) was similar in essential features to that of the ester, showing signals due to C-17-C-18 at  $\delta$  6.1 and 5.7 (doublets,  $J_{17,18} = 9.0$  cps) and C-8  $\alpha$ H at  $\delta$  1.13 ( $J_{8\alpha,8\beta} = 13.0$  cps), as well as signals due to two aromatic H, two different methoxys, and the N-methyl group. The phenolic hydroxyl group was located by a signal at  $\delta$  8.38 in dimethyl sulfoxide. The infrared spectrum of the nitrile, like that of the above ester, but unlike the spectra of the ketone VIII and isonepenthone, in solution showed hydroxyl absorption at  $3545\text{ cm}^{-1}$ .

The nmr spectrum of the alcohol II ( $R' = H$ ,  $R = n\text{-Pr}$ ),<sup>7</sup> isolated as a minor product from the products of the reaction of the ketone I with *n*-propylmagnesium halides, was also similar to that of the ester X ( $R = Et$ ,  $R' = H$ ) showing signals (in  $\delta$  units) for the following: phenolic OH, 5.93 (exchangeable); C-18 H, C-17 H, 6.00 and 5.64 (doublets,  $J_{17,18} = 9$  cps); alcohols OH 4.72 (exchangeable); C-5 H, 3.0; C-8  $\alpha$ H, 0.70 (doublet,  $J_{8\alpha,8\beta} = 11$  cps), in addition to the expected signals for the other systems present in structure II ( $R' = H$ ,  $R = n\text{-Pr}$ ).

The products of the rearrangements set out above, *i.e.*, the bases of general structures II, V, VIII, X, and XII, are all unstable to acids and readily suffer hydrolysis. The ketones VIII and VIII ( $\text{CH}_3 = \text{Ph}$ ), being both mixed ketals and allylic phenyl ethers, on treatment with acids under mild conditions are converted into the phenolic  $\alpha,\beta$ -unsaturated ketones VII ( $R' = H$ ) and VII ( $R' = H$ ,  $\text{CH}_3 = \text{Ph}$ , *i.e.*,  $\psi$ -nepenthone). Both of the nonphenolic parent ketones, which are prepared under conditions of reversible enolization, may be assumed to be the stable isomers, which are shown by the examination of models to have the  $\text{COCH}_3$  or  $\text{COPh}$  group disposed as shown in formula VIII. The examination of models of  $\psi$ -nepenthone (VII,  $R' = H$ ,  $\text{CH}_3 = \text{Ph}$ ), however, suggests that in this base there is little difference in stability between the two C-18 isomers. In support of this view it has been found that  $\psi$ -nepenthone produced by the mild acid hydrolysis of isonepenthone (VIII,  $\text{CH}_3 = \text{Ph}$ ) is a single substance, presumably the  $18\beta$  isomer, which can be equilibrated on standing in acid solution to an approximately 1:1 mixture of two bases<sup>8</sup> which can be differentiated on alumina plates. The extraction of the separate zones on the alumina with methanol, however, results in re-equilibration of the isomers, and the C-18 epimer of  $\psi$ -nepenthone has not been isolated. The examination of models of the epimeric forms of the ketone VII ( $R' = H$ ), however, suggests that the  $18\alpha$  isomer will be the more stable of the two, since in this form non-bonded interactions are minimal, whereas in the  $18\beta$  ketone there is appreciable interaction between the methyl group in the side chain and one of the C-15 hydrogen atoms. The hydrolysis of the ketal VIII takes place without the separation of a hydrochloride, *i.e.*, under conditions similar to those required for the equilibration of  $\psi$ -nepenthone, and gives a single substance, which is assigned the  $18\alpha$  structure on the basis of its very ready cyclization to the base XXV (see below).

The ketone V ( $R' = \text{Me}$ ) is an aldol methyl ether as well as a highly strained (cyclopropane) derivative, and

(8) This observation was made by Dr. J. W. Lewis and Mr. M. J. Readhead of this laboratory.

is readily hydrolyzed by acids under very mild conditions. Since this reaction must proceed through the enol form of the ketone, the product is the stable C-18 epimer, identical with the product of methylation of the phenol VII ( $R' = H$ ).

The rearranged nitriles and esters of general structures XII and X are likewise very readily hydrolyzed with production of the corresponding  $\alpha,\beta$ -unsaturated ketones XI ( $R = \text{CN}$ ) or XI ( $R = \text{COOR}$ ). The ease with which the hydrolysis of the bases V, X, and XII occurs contrasts markedly with the stability of the ketones I and also I ( $\text{CH}_3 = \text{Ph}$ ) and the ester I ( $\text{CH}_3 = \text{OEt}$ ) under acid conditions.<sup>9</sup> This may be the result of strain in the cyclopropane ring, but it may be noted that a similar difference in stability has been observed in the enol ether systems of thebaine and dihydrothebaine, in which the 4,5-oxygen bridge is intact, which form stable hydrochlorides, and the phenolic bases dihydrothebaine- $\varphi$ ,<sup>10</sup>  $\beta$ -dihydrothebaine, thebainone-A enol methyl ether,<sup>10</sup> and the  $\Delta^5$ - and  $\Delta^6$ -enol methyl ethers of dihydrothebainone,<sup>10</sup> all of which are extremely rapidly hydrolyzed, even by cold acetic acid.

The ketone V ( $R' = \text{Me}$ ), which is stable to bases, reacts normally with Grignard reagents, giving tertiary alcohols of general structure II ( $R' = \text{Me}$ ), and these, like the corresponding phenols II ( $R' = H$ ), on treatment with acid very readily suffer dehydration and hydrolysis to give the olefinic ketones III. This reaction is essentially the same as that involved in the conversion of alcohols of structure XIII into 14-alkenylcodeinones (XIV),<sup>11</sup> but occurs under much milder conditions. The bases III ( $R = \text{Me}$ ,  $R' = H$ ) and III ( $R = R' = \text{Me}$ ), obtained in this way, are identical with the stable phenolic end product of acid-catalyzed rearrangement of the alcohol XIII ( $R = \text{Me}$ ) or the alkenylcodeinone XIV ( $R = \text{Me}$ ) and its methyl ether.<sup>11</sup>

(9) This phenolic,  $\alpha,\beta$ -unsaturated ketone VII ( $R = H$ ) is the product of the action of boron tribromide on the ketone I at  $5^\circ$ . The reaction can be rationally represented by the mechanism set out in i, which involves no disturbance of stereochemistry at C-7 [becoming C-18 in the diketone VIII ( $R = H$ )], and is analogous to the flavothebaine rearrangement.

Hofmann degradation to a base showing styrenoid ultraviolet absorption and carbonyl absorption in the infrared only at  $1740\text{ cm}^{-1}$ .

The nmr spectrum of this base in deuterochloroform showed signals (in  $\delta$  units) at 6.70 (two aromatic H), 6.45 (doublet, C-9 CH=,  $J_{9,10} = 9.0$  cps), 5.97 (doublet, C-10 CH=,  $J_{9,10} = 9.0$  cps), 5.42 (two olefinic H), 3.92 (C-3 OCH<sub>3</sub>), and 2.30 (2NCH<sub>3</sub>). This spectrum, which clearly shows that the COCH<sub>3</sub> system of the phenol VII (R' = H) is no longer present in the new base, coupled with the infrared spectrum which shows the absence of an  $\alpha,\beta$ -unsaturated ketone system, and the presence of a carbonyl group very probably in a five-membered ring, leads to the structure XXIV for the new base. Further examination of the nmr spectrum in deuterochloroform containing deuteriobenzene<sup>7</sup> resulted in resolution of the two aromatic proton signals and also of the signal at  $\delta$  5.42, which was resolved into a barely defined double doublet with centers at  $\delta$  5.63 and 5.40 ( $J = ca. 9.0$  cps), attributed to the C-7 and C-8 protons. In this spectrum the C-5 proton was located as a doublet at  $\delta$  3.50 ( $J_{5,18} = 9.0$  cps), and the C-20 protons were located as doublets at  $\delta$  2.95 and 2.58 ( $J_{20,20} = 16$  cps). The base XXIV obviously results from the Hofmann degradation of the methiodide of the base VII (R' = H) and base-catalyzed ketolization of the COCH<sub>3</sub> and C-6 carbonyl groups.

A model of XXIV can be constructed without strain, and as the parent base containing an intact nitrogen-containing ring is also strain-free, the action of alkalis on the diketone VII (R' = H) was studied. This results in the production of the base XXV, Hofmann degradation of the methiodide of which yields the methine base XXIV. The ketolization can only occur with one arrangement of the COCH<sub>3</sub> group, and the stable ketone VII (R' = H) may confidently be assumed to be the 18 $\alpha$  form shown. The phenol VII (R' = H) and its methyl ether VII (R' = Me) give deep orange solutions in alkalis and this color fades as the cyclization of the ketone VII (R' = H) proceeds. The color is, therefore, assumed to be that of the enolate ion, in which some interaction between the enone and enol systems must occur, and it may be noted that the color is similar to that of flavothebaine in alkaline solution.<sup>18</sup>

(16) K. W. Bentley, J. Dominguez, and J. P. Ringe, *J. Org. Chem.*, **22**, 418 (1957).

The methyl ether VII (R' = Me) of the phenol VII (R' = H) is recovered unchanged from alkaline solution, and methylation of the ketol XXV in alkali results in deketolization and the production of the diketone VII (R' = Me). The examination of a model of the base XXV shows that the hydroxyl groups at C-4 and C-6 are in very close proximity and the stability of the phenol in alkalis may be attributed to inhibition by the phenate anion of the removal of a proton from the C-6 hydroxyl group, which is an essential first step in the deketolization. Indeed, the proton of the C-6 hydroxyl may be expected to form a very firm hydrogen bond with the C-4 oxygen atom when the latter acquires a negative charge in alkaline solution. In the methyl ether of the phenol XXV, however, there will be no electrostatic inhibition of the removal of the proton of the C-6 hydroxyl group and deketolization can proceed.

## Experimental Section

**18-Acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylthebaine (VIII) (Isothevinone).** a. 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (50 g) was boiled under reflux with potassium hydroxide (50 g) in methanol (500 ml) and water (100 ml) for 1 hr, during which time crystalline material separated. The mixture was diluted with water (100 ml) and cooled, and the solid was collected, when isothevinone (VIII) (40 g) was obtained as pale cream prisms, mp 168° raised to 170° on recrystallization from ethanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . Anal. Calcd for C<sub>22</sub>H<sub>27</sub>NO<sub>4</sub>: C, 72.4; H, 7.1. Found: C, 72.3; H, 7.1.

The base was alkali insoluble and the alkaline suspension gave only a pale pink coloration with diazotized sulfanilic acid.

b. The same base was obtained in the same way by the rearrangement of 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine.

**7-Acetyl-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethylthebaine (V, R' = Me).** a. 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (10 g) in dry *i*-butyl alcohol (20 ml) was added to a solution of potassium (1.1 g) in dry *i*-butyl alcohol (30 ml) and the mixture heated at 50° for 10 min. Methyl iodide (3.5 g, 0.95 mole) was then added and the mixture stirred for 15 min, after which it was poured into water and the product isolated by ether extraction. Evaporation of the dried extracts yielded a viscous yellow gum that crystallized on standing. Recrystallization of the product from petroleum ether (bp 80–100°) afforded the base V (R' = Me) as pale cream prisms, mp 116°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$ .

Anal. Calcd for C<sub>24</sub>H<sub>29</sub>NO<sub>4</sub>: C, 73.0; H, 7.3. Found: C, 73.1; H, 7.3.

Acid hydrolysis of this base afforded 18-acetyl-5,14-ethano-4-O-methylthebaine (VII, R' = Me) (see below).

b. 18-Acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylthebaine (VIII) (32 g) (prepared by the alkaline rearrangement of 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine) in *i*-butyl alcohol (100 ml) was added to a solution of potassium (12 g) in *i*-butyl alcohol (200 ml), and the mixture was stirred for 10 min at 50°. Methyl iodide (40 g) was added to the mixture which was stirred for 2 hr. The precipitated sodium iodide was removed by filtration, and the mixture was evaporated to dryness, the residue being thoroughly extracted with ether. The ether extract on evaporation afforded a viscous oil, which crystallized on standing. Recrystallization of the product from petroleum ether (bp 80–100°) afforded 7-acetyl-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethylthebaine (V, R' = Me) as pale cream prisms, mp 115–116°, identical (mixture melting point and infrared spectrum) with material prepared as described above.

**18-Acetyl-5,14-ethanothebaine (VII, R' = H) ( $\psi$ -Thevinone).** 18-Acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylthebaine (isothevinone, VIII) (20 g) was dissolved in 2 *N* hydrochloric acid (100 ml) and the solution was basified with ammonia, when the diketone VII (R' = H) (18 g) was precipitated. The product was collected, washed, and recrystallized from methanol, when it was obtained as white prisms, mp 200°,  $\nu_{\max}$  1715 and 1690  $\text{cm}^{-1}$ .

Anal. Calcd for C<sub>22</sub>H<sub>25</sub>NO<sub>4</sub>: C, 71.9; H, 6.8. Found: C, 71.1; H, 6.9.

From aqueous 2-ethoxyethanol the hydrated base separated as prisms, mp 169–170°.

al. Calcd for  $C_{22}H_{31}NO_4 \cdot H_2O$ : C, 68.6; H, 7.0. Found: 7; H, 6.9.

is base was readily soluble in alkali to give a yellow solution which gave a blood red color with diazotized sulfanilic acid.

methiodide, prepared from the base, methyl iodide, and anol under reflux for 2 days, was precipitated with ether and utilized from methanol-ether and then from ethanol, when it obtained as white prisms, mp 202–205°.

al. Calcd for  $C_{22}H_{31}NO_4 \cdot CH_3I \cdot H_2O$ : C, 52.3; H, 5.7. d: C, 52.1; H, 6.0.

oxime was obtained as prisms, mp 253–255°, from ethanol.

al. Calcd for  $C_{22}H_{31}N_2O_4$ : C, 69.1; H, 6.9; N, 7.2. Found: 6; H, 7.1; N, 7.2.

**Acetyl-5,14-ethano-4-O-methylthebainone (VII, R' = Me).** Methyl sulfate (40 g) was slowly added to a vigorously stirred solution of 18-acetyl-5,14-ethanothebainone (VII, R' = H) and potassium hydroxide (20 g) in water. The product was obtained as a cream solid (48 g) which was collected and recrystallized from aqueous 2-ethoxyethanol, when the methyl ether V (R' = Me) (35 g) was obtained as white prisms, mp 183°,  $\nu_{\max}$  1690  $cm^{-1}$ .

al. Calcd for  $C_{22}H_{31}NO_4$ : C, 72.4; H, 7.1. Found: C, 72.4; H, 7.2.

base was insoluble in alkali.

methiodide was prepared by boiling the base in methyl iodide under reflux for 4 days, and was obtained from ethanol as prisms, mp 202–205°.

al. Calcd for  $C_{22}H_{31}NO_4 \cdot CH_3I \cdot 0.5H_2O$ : C, 54.1; H, 5.8. d: C, 54.0; H, 5.7.

oxime was obtained as prisms, mp 247–248°, from ethanol.

al. Calcd for  $C_{22}H_{31}N_2O_4$ : C, 69.7; H, 7.1; N, 7.1. Found: 9; H, 7.4; N, 7.1.

**7-Acetyl-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethyldihydrothebainol (V, R' = Me) (1 g)** was dissolved in 2 N hydrochloric acid (10 ml) and the solution basified with ammonia. The precipitated solid was collected and recrystallized from aqueous 2-ethoxyethanol, when 18-acetyl-5,14-ethano-4-O-methylthebainone (R' = Me), mp 183°, was obtained identical with material used as in the preceding paragraph (mixture melting point and infrared spectrum).

**5,14-Ethano-4(O)-6-dehydro-18-(1-hydroxyethyl)-6-O-methylthebainol (IX, R = H) (Isothevinol).** Sodium borohydride (0.5 g) was added to a solution of 18-acetyl-4(O)-6-dehydro-5,14-ethano-6-methylthebainol (VIII) (10 g) in 2-ethoxyethanol (20 ml), and the mixture was heated at 100° for 30 min. The resulting solution was cooled, and the solid (9 g) was collected and recrystallized from aqueous 2-ethoxyethanol, when the secondary alcohol IX (R = H) was obtained as white prisms, mp 215°.

al. Calcd for  $C_{22}H_{31}NO_4 \cdot H_2O$ : C, 68.8; H, 7.7. Found: 7; H, 7.8.

carbonyl absorption showed in the infrared. The base was insoluble, and the suspension in alkali gave no color with diazotized sulfanilic acid.

**14-Ethano-18-(1-hydroxyethyl)thebainone (VI, R = H).** 5,14-Ethano-4(O)-6-dehydro-18-(1-hydroxyethyl)-6-O-methylthebainol (IX, R = H) (10 g) was dissolved in 2 N hydrochloric acid (100 ml), and the resulting solution was basified with ammonia. The precipitated base was collected (9 g) and recrystallized from aqueous 2-ethoxyethanol, when the keto alcohol VI (R = H) was obtained as white prisms, mp 248°,  $\nu_{\max}$  1690  $cm^{-1}$ .

al. Calcd for  $C_{22}H_{31}NO_4 \cdot H_2O$ : C, 68.3; H, 7.5. Found: 5; H, 7.3.

base was readily soluble in alkali, and the solution gave a blood red color with diazotized sulfanilic acid.

Sodium borohydride (0.1 g) was added to a suspension of 18-acetyl-5,14-ethanothebainone (2 g) in ethanol (10 ml) and the solution stirred at 25° for 15 min. Water (50 ml) was added, and the mixture was stirred until crystallization was complete, and the crystals were then collected. Recrystallization of the product from aqueous ethanol afforded the secondary alcohol VI (R = H) identical with material prepared as above, mp and mmp 248°,  $\nu_{\max}$  1690  $cm^{-1}$ .

**5,14-Ethano-18-(1-hydroxyethyl)-4-O-methylthebainone.** 18-Acetyl-5,14-ethano-4-O-methylthebainone (VII, R' = Me) (10 g) was reduced as above with sodium borohydride (0.5 g) in methanol. The solvent was removed and the residue crystallized on a silica gel. The product was recrystallized from methanol, when it obtained as white prisms, mp 271°,  $\nu_{\max}$  1690  $cm^{-1}$ .

al. Calcd for  $C_{22}H_{31}NO_4 \cdot 0.5H_2O$ : C, 70.4; H, 7.7. Found: 7; H, 7.5.

The same base was obtained by the O-methylation of the phenol VI (R = H) in aqueous methanolic potassium hydroxide, with methyl sulfate, as an oil on removal of most of the methanol *in vacuo*.

**Catalytic Reduction of 18-Acetyl-4(O)-6-dehydro-5,14-ethano-6-O-methylthebainol (VIII).** a. A suspension of the ketone VIII (20 g) in 2-ethoxyethanol (200 ml, distilled from sodium) was shaken under hydrogen at 20° (55 psi) in the presence of 5% rhodium on alumina (1 g) for 3 hr. By the end of that time the base had dissolved and uptake of hydrogen had ceased. The solution was filtered and evaporated, and the residual solid was recrystallized from ethanol (100 ml), when 18-acetyl-4(O)-6-dehydro-5,14-ethano-6-O-methyldihydrothebainol (XVI) (14 g) was obtained as white prisms, mp 158–160°,  $\nu_{\max}$  1715  $cm^{-1}$ .

Anal. Calcd for  $C_{22}H_{31}NO_4$ : C, 72.0; H, 7.6; N, 3.7. Found: C, 72.0; H, 7.6; N, 3.8.

The base was insoluble in alkali and the suspension gave only a pale pink coloration with diazotized sulfanilic acid.

b. A suspension of the ketone VIII (10 g) in 2-ethoxyethanol (200 ml) was shaken under hydrogen at 20° (55 psi) in the presence of 10% palladized charcoal (0.5 g) for 2 hr after which time hydrogen absorption had ceased. Evaporation of the filtered solution gave an oil which was dissolved in ether (50 ml), when a crystalline solid separated (6.2 g). This was found to be a mixture of the dihydro compound XVI (see above) and 18-acetyl-5,14-ethanodihydrothebainone- $\Delta^4$ -enol methyl ether (XV) from which the latter (3.4 g) was recovered by recrystallization from ethanol, rapid washing of the crystals with two 20-ml portions of ether, and further recrystallization from ethanol. In this way it was obtained as white prisms, mp 161–163°,  $\nu_{\max}$  1700 and 1675  $cm^{-1}$  (C=O enol ether).

Anal. Calcd for  $C_{22}H_{31}NO_4$ : C, 72.0; H, 7.6. Found: C, 72.1; H, 7.4.

An alkaline solution of the base gave a blood red color with diazotized sulfanilic acid.

**Rearrangement of 7 $\alpha$ -Acetyl-6,14-endo-ethanotetrahydrothebaine (I, CH=CH=CH<sub>2</sub>CH<sub>2</sub>).** Potassium hydroxide (8.8 g) was added to a hot solution of 7 $\alpha$ -acetyl-6,14-endo-ethanotetrahydrothebaine (8.8 g) in methanol (88 ml), and the mixture was boiled under reflux for 1 hr, evaporated to 45 ml, and poured into ice-water (350 ml). The precipitated solid (8.2 g) was collected and recrystallized from petroleum ether (bp 40–60°) to give 18-acetyl-4(O)-6-dehydro-5,14-methyldihydrothebainol (XVI) (4.5 g) as prisms, mp 155–157° raised to 158–160° on recrystallization from methanol. This base was identical in melting point, mixture melting point, and infrared absorption with that obtained by the catalytic reduction of 18-acetyl-4(O)-6-dehydro-5,14-ethano-6-O-methylthebainol (VIII) over rhodium on alumina.

**18-Acetyl-5,14-ethanodihydrothebainone (XIX).** a. 18-Acetyl-4(O)-6-dehydro-5,14-ethano-6-O-methyldihydrothebainol (XVI) (5 g) was dissolved in 1 N hydrochloric acid (100 ml) and after 1 hr crystalline 18-acetyl-5,14-ethanodihydrothebainone hydrochloride was collected, mp 197–198°.

Anal. Calcd for  $C_{22}H_{31}NO_4 \cdot HCl \cdot H_2O$ : C, 62.3; H, 7.1; Cl, 8.4; N, 3.3. Found: C, 61.7; H, 7.6; Cl, 8.0; N, 3.2.

The free base was recovered by treating the salt with sodium bicarbonate solution and extracting with chloroform. On recrystallization from ethanol it was obtained as white prisms, mp 205–207°,  $\nu_{\max}$  1720 and 1705  $cm^{-1}$ .

Anal. Calcd for  $C_{22}H_{31}NO_4$ : C, 71.5; H, 7.4; N, 3.8. Found: C, 71.3; H, 7.5; N, 3.8.

b. The same base, mp 205–207°, undepressed on mixing with material prepared as in a, was obtained in the same way by the hydrolysis of 18-acetyl-5,14-ethanodihydrothebainone- $\Delta^4$ -enol methyl ether (XV) with 1 N hydrochloric acid. It is most convenient to prepare the base by the hydrolysis of the mixture of bases XV and XVI obtained by the reduction of 18-acetyl-4(O)-6-dehydro-5,14-ethano-6-O-methylthebainol over palladized charcoal.

**18-Acetyl-5,14-ethano-4-O-methyldihydrothebainone (XIX, OH = OMe).** The mixture of bases (5 g) from the hydrogenation of the ketone VIII was dissolved in the minimum amount of 2 N hydrochloric acid, and the solution was diluted to 70 ml. Sodium hydroxide solution (2 N) was added until the precipitate redissolved followed by a further 50 ml. Dimethyl sulfate (5 ml) was then added and the mixture shaken for 1 hr, after which the solid was collected, washed with water, and recrystallized from ethanol, when the diketone XIX (OH = OMe) (2 g) was obtained as white prisms, mp 165–166°. Anal. Calcd for  $C_{22}H_{31}NO_4$ : C, 72.0; H, 7.6; N, 3.7. Found: C, 71.8; H, 7.7; N, 3.7.

**4-(O)-6-Dehydro-5,14-ethano-18-(1-hydroxyethyl)-6-O-methyl dihydrothebainol (XVII).** Sodium borohydride (3 g) was added in portions over 15 min to a solution of 18-acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylthebainol (XVI) (5 g) in 2-ethoxyethanol (50 ml) at 20°. The mixture was heated at 100° for 15 min, cooled, diluted with 2 *N* ammonia solution, and extracted with chloroform. The chloroform extract was evaporated and the residue recrystallized from ethanol, when the secondary alcohol XVII was obtained as white prisms, mp 165–166°.

*Anal.* Calcd for  $C_{25}H_{31}NO_4$ : C, 71.7; H, 8.1. Found: C, 71.8; H, 8.3.

**5,14-Ethano-18-(1-hydroxyethyl)dihydrothebainone (VI, R = H, CH=CH=CH<sub>2</sub>CH<sub>2</sub>).** 4-(O)-6-Dehydro-5,14-ethano-18-(1-hydroxyethyl)-6-O-methyldihydrothebainol (XVII) (0.5 g) was dissolved in 2 *N* hydrochloric acid (5 ml), and the solution was kept at room temperature for 30 min and in the refrigerator overnight. The solid was collected and recrystallized from water, when 5,14-ethano-18-(1-hydroxyethyl)dihydrothebainone hydrochloride was obtained as white prisms, mp 257° dec,  $\nu_{\max}$  1720 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{25}H_{31}NO_4 \cdot HCl \cdot 3H_2O$ : C, 57.2; H, 7.9. Found: C, 57.0; H, 8.0.

**Rearrangement of N-Allyl-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine (I, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>) (N-Allylnorthevinone).** A solution of potassium hydroxide (4.8 g) in methanol (50 ml) was added slowly to a boiling solution of N-allyl-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine hydrochloride (11 g) in methanol (50 ml) and the mixture then boiled under reflux for 1 hr. The solution was diluted with water and extracted with chloroform to give a mixture of two bases (11 g). The product (8 g) was crystallized from methanol to give N-allyl-18-acetyl-5,14-ethanonorthebainone dimethyl ketal (XVIII) (2.6 g) as prisms, mp 106–107°,  $\nu_{\max}$  1715 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{25}H_{31}NO_4$ : C, 71.0; H, 7.6; N, 3.2. Found: C, 70.6; H, 7.7; N, 3.5.

The mother liquor from this crystallization was diluted with water, and the precipitated solid was recrystallized from aqueous methanol, when N-allyl-18-acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylnorthebainol (VIII, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>) (1.1 g) was obtained as white prisms, mp 129–130°,  $\nu_{\max}$  1715 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{25}H_{31}NO_4$ : C, 73.7; H, 7.2; N, 3.4. Found: C, 73.3; H, 7.0; N, 3.7.

**N-Allyl-18-acetyl-5,14-ethanonorthebainone (VII, R' = H, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>).** The above two bases XVIII (R = CH<sub>2</sub>CH=CH<sub>2</sub>) and VIII (NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>) obtained by the rearrangement of the ketone I (NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>), separately or together, on hydrolysis with 2 *N* hydrochloric acid followed by precipitation with ammonia and recrystallization of the product from ethanol, afforded the diketone VII (R' = H, NMe = NCH<sub>2</sub>CH=CH<sub>2</sub>) as prisms, mp 110–112°,  $\nu_{\max}$  1715 and 1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{27}NO_4 \cdot 0.5H_2O$ : C, 71.4; H, 6.8; N, 3.6. Found: C, 71.6; H, 7.0; N, 3.5.

**Rearrangement of N-Propargyl-7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine (I, NMe = NCH<sub>2</sub>C $\equiv$ CH).** The hydrochloride of the ketone I (NMe = NCH<sub>2</sub>C $\equiv$ CH) (10 g) was boiled with potassium hydroxide (4.8 g) in methanol (100 ml) for 1 hr. The product was isolated by chloroform extraction and crystallized from methanol, when N-propargyl-18-acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylnorthebainol (VIII, NMe = NCH<sub>2</sub>C $\equiv$ CH) was obtained as prisms, mp 177–179°.

*Anal.* Calcd for  $C_{25}H_{27}NO_4$ : C, 74.0; H, 6.7. Found: C, 73.7; H, 6.7.

**N-Propargyl-18-acetyl-5,14-ethanonorthebainone (VII, R' = H, NMe = NCH<sub>2</sub>C $\equiv$ CH).** N-Propargyl-18-acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylnorthebainol (VIII, NMe = NCH<sub>2</sub>C $\equiv$ CH) (2 g) was dissolved in warm 2 *N* hydrochloric acid, and after 5 min the solution was basified with ammonia. The product was collected and recrystallized from methanol when the diketone VII (R' = H, NMe = NCH<sub>2</sub>C $\equiv$ CH) was obtained as prisms, mp 114°,  $\nu_{\max}$  1715 and 1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{25}NO_4 \cdot H_2O$ : C, 70.4; H, 6.6; N, 3.4. Found: C, 70.4; H, 6.7; N, 3.9.

**Base-Catalyzed Rearrangements Accompanying Normal Grignard Reactions with the Ketone I and Its 6,14-Ethano Analog.** a. 7 $\beta$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (0.5 g) in anhydrous ether (100 ml) was added to a solution of methylmagnesium iodide (from 0.17 g of magnesium) in ether (25 ml), and the mixture was heated under reflux for 1 hr. The mixture was then poured into aqueous ammonium chloride, and the ether layer was separated, dried over magnesium sulfate, and evaporated, to leave a crude

product (0.5 g) shown by thin layer chromatography to consist of two components. These were separated on alumina plates using ether as developing solvent. The less polar material (125 mg) was recovered from the plate and obtained as white prisms, mp 215°, from methanol,  $\nu_{\max}$  3545, 3490 cm<sup>-1</sup>, and identified as 5,7-dehydro-6,14-endo-etheno-7-(1-hydroxy-1-methylethyl)-6-O-methyldihydrothebainol (II, R = Me, R' = H), by hydrolysis with cold 2 *N* hydrochloric acid to 5,14-ethano-18-isopropylidenethebainone (III, R = Me, R' = H), identical in melting point, mixture melting point, and infrared absorption with an authentic specimen.

b. The product of the reaction between 7 $\alpha$ -acetyl-6,14-endo-ethenotetrahydrothebaine (38 g) and *n*-propylmagnesium iodide was dissolved in methanol and cooled, and the crystalline 6,14-endo-etheno-7 $\alpha$ -(1-(*R*)-hydroxy-1-methylbutyl)tetrahydrothebaine (XIII, R = *n*-Pr)<sup>4</sup> was collected. The mother liquors were concentrated to yield 11.1 g of a glass, a sample of which (1.08 g) was subjected to partition chromatography on Celite using a methanol-heptane system, with observation of the extinction of the eluate at 230 m $\mu$ . Three main fractions were obtained, yielding 0.15 g (A), 0.25 g (B), and 0.65 g (C) of product on evaporation. Fraction A consisted of the tertiary alcohol XIII (R = *n*-Pr) and fraction C consisted of the secondary alcohol XIII (R = H), resulting from Grignard reduction of the ketone I.<sup>4</sup>

Fraction B was dissolved in benzene and rechromatographed on alumina (25 g) which was eluted successively with 100-ml portions of 1, 5, 20, 50, and 100% ethyl acetate in benzene. Fractions of 20 ml were collected and examined by thin layer chromatography, similar fractions being combined. Fractions 11–13 gave 96 mg of a mixture of 7 $\alpha$ - and 7 $\beta$ -acetyl-6,14-endo-ethenotetrahydrothebaine and fractions 18–22 gave 176 mg of an oil, which on trituration with methanol gave 5,7-dehydro-6,14-endo-etheno-7-(1-hydroxy-1-methylbutyl)-6-O-methyldihydrothebainol (II, R = *n*-Pr, R' = H) (36 mg), mp 192–198°, raised to 202–203° on recrystallization from methanol.

*Anal.* Calcd for  $C_{25}H_{31}NO_4$ : C, 73.4; H, 8.3; N, 3.3. Found: C, 73.1; H, 8.35; N, 3.8.

c. The crude product of the reaction between 7 $\alpha$ -acetyl-6,14-endo-ethanotetrahydrothebaine (I, 6,14-CH<sub>2</sub>CH<sub>2</sub>) (140 g) and isopropylmagnesium chloride (from 48.6 g of magnesium), in ether and benzene solution, which was noncrystalline, was triturated with cold methanol. The solid so formed was collected, and extracted with boiling ethanol (300 ml), and the undissolved matter was crystallized from chloroform. In this way 5,7-dehydro-6,14-endo-ethano-7-(1-hydroxy-1,2-dimethylpropyl)-6-O-methyldihydrothebainol (II, R = *i*-Pr, R' = H, 6,14-CH<sub>2</sub>CH<sub>2</sub>) was obtained as white prisms, mp 253–256°.

*Anal.* Calcd for  $C_{25}H_{27}NO_4$ : C, 73.1; H, 8.7; N, 3.3. Found: C, 72.7; H, 8.3; N, 3.5.

d. In like manner to that described in part c above, the following were isolated from the products of reaction of 7 $\alpha$ -acetyl-6,14-endo-ethanotetrahydrothebaine and the appropriate Grignard reagent: 5,7-dehydro-6,14-endo-ethano-7-(1-hydroxy-1-methylpentyl)-6-O-methyldihydrothebainol (II, R = *n*-Bu, R' = H, 6,14-CH<sub>2</sub>CH<sub>2</sub>, prisms, mp 169–170°. *Anal.* Calcd for  $C_{27}H_{33}NO_4$ : C, 73.4; H, 8.9; N, 3.2. Found: C, 72.9; H, 8.7; N, 3.3; 5,7-dehydro-6,14-endo-ethano-7-(1-hydroxy-1-methylpropyl)-6-O-methyldihydrothebainol (II, R = Et, R' = H, 6,14-CH<sub>2</sub>CH<sub>2</sub>, white prisms, mp 215–216°. *Anal.* Calcd for  $C_{27}H_{33}NO_4$ : C, 72.6; H, 8.5; N, 3.4. Found: C, 72.8; H, 8.5; N, 3.4; and 5,7-dehydro-6,14-endo-ethano-7-(1-hydroxy-1,4-dimethylpentyl)-6-O-methyldihydrothebainol (II, R = *i*-Am, R' = H, 6,14-CH<sub>2</sub>CH<sub>2</sub>, white prisms, mp 178–179°. *Anal.* Calcd for  $C_{28}H_{35}NO_4$ : C, 73.8; H, 9.1; N, 3.1. Found: C, 73.5; H, 8.9; N, 3.2).

**5,14-Ethano-18-(3'-methylbut-2'-ylidene)dihydrothebainone (III, R = *i*-Pr, R' = H, 7,8-dihydro).** 5,7-Dehydro-6,14-endo-ethano-7-(1-hydroxy-1,2-dimethylpropyl)-6-O-methyldihydrothebainol (II, R = *i*-Pr, R' = H, 6,14-CH<sub>2</sub>CH<sub>2</sub>) (0.1 g) was dissolved in 15 *N* hydrochloric acid (2.5 ml), and the solution was heated on the water bath for 10 min. A crystalline hydrochloride separated and was collected and recrystallized from water, when it was obtained as white prisms, mp 199–201°,  $\nu_{\max}$  1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{25}H_{31}NO_4 \cdot HCl \cdot 3H_2O$ : C, 61.7; H, 8.3. Found: C, 61.2; H, 8.3.

**4-(O)-6-Dehydro-5,14-ethano-18-(1-hydroxy-1-methylethyl)-6-O-methylthebainol (IX, R = Me) (Methylisothevinol).** A solution of methylithium (4 g) in ether (125 ml) was slowly added to a vigorously stirred solution of 18-acetyl-4-(O)-6-dehydro-5,14-ethano-6-O-methylthebainol (VIII) (35 g) in ether (200 ml), under nitrogen,

rate sufficient to maintain boiling. The mixture was finally cooled under reflux for 30 min and then diluted cautiously with ether (250 ml). The ether layer on evaporation afforded 34.9 g solid matter, still containing some ketone (infrared spectrum), this was treated under the same conditions with a further 4 g methyl lithium. Evaporation of the ether layer then gave non-melting material from which the tertiary alcohol IX ( $R = Me$ ) (27.8 g) was recovered on recrystallization from ethanol as white prisms, mp 117–118°.

*Anal.* Calcd for  $C_{24}H_{32}NO_4$ : C, 72.5; H, 7.9; N, 3.5. Found: C, 72.2; H, 8.1; N, 3.4.

**Hydrolysis of 4-(O)-6-Dehydro-5,14-ethano-18-(1-hydroxy-1-methylethyl)-6-O-methylthebainol (Methylisothevinol, IX,  $R = Me$ ).** The tertiary alcohol IX ( $R = Me$ ) (3 g) was dissolved in 1 *N* hydrochloric acid (100 ml), and the solution was kept at 25° for 10 min. Neutralization of the solution with sodium bicarbonate followed by isolation of the product by ether extraction gave 5,14-ethano-18-(1-hydroxy-1-methylethyl)thebainone (VI,  $R = Me$ ) (2.2 g), which was obtained from aqueous ethanol as rosettes of white crystals, mp 129–132°,  $\nu_{max}$  (CCl<sub>4</sub> solution) 3615 (free tertiary OH), 3450 (phenolic OH), and 1670 cm<sup>-1</sup> ( $\alpha,\beta$ -unsaturated carbonyl).

*Anal.* Calcd for  $C_{23}H_{29}NO_4 \cdot H_2O$ : C, 68.8; H, 7.8. Found: C, 68.9; H, 7.7.

The tertiary carbinol IX ( $R = Me$ ) (1.5 g) was boiled under reflux for 30 min with 5 *N* hydrochloric acid (25 ml), and the mixture cooled and diluted with water (25 ml). The crystalline solid obtained was collected (1.4 g) and recrystallized from water, giving 5,14-ethano-18-isopropylidenethebainone (III,  $R = Me$ ,  $R' = H$ ) hydrochloride as white prisms, mp 320°.

*Anal.* Calcd for  $C_{23}H_{27}NO_4 \cdot HCl$ : C, 68.7; H, 7.0; Cl, 8.8. Found: C, 68.4; H, 7.0; Cl, 8.7.

The free base crystallized readily only from methanol, when it was obtained as solvated prisms, mp 138–139°,  $\nu_{max}$  (CCl<sub>4</sub> solution) 3532 (phenolic OH), and 1690 cm<sup>-1</sup> ( $\alpha,\beta$ -unsaturated carbonyl). The base coupled with diazotized sulfanilic acid in alkaline solution. The base and its hydrochloride were identical in infrared absorption and in behavior on thin layer chromatography with 5,14-ethano-18-isopropylidenethebainone and its hydrochloride prepared by the acid-catalyzed rearrangement of 6,14-etheno-7 $\alpha$ -(1-hydroxy-1-methylethyl)tetrahydrothebaine (XIII,  $Me$ ).<sup>11</sup>

**Hydration of 5,14-Ethano-18-(1-hydroxy-1-methylethyl)thebainol (VI,  $R = Me$ ).** The tertiary alcohol VI ( $R = Me$ ) (120 mg) was boiled under reflux with 5 *N* hydrochloric acid (5 ml) for 30 min.

The solution was cooled; the crystalline solid was collected, shaken with sodium bicarbonate solution and ether. Evaporation of the ether and crystallization of the product from methanol gave 5,14-ethano-18-isopropylidenethebainone (III,  $R = Me$ ,  $R' = H$ ), identical in infrared absorption with material prepared by the acid-catalyzed rearrangement of the tertiary alcohol (III,  $R = Me$ ).<sup>11</sup>

**5,7-Dehydro-6,14-endo-etheno-7-(1-hydroxy-1-methylethyl)-4,6-dimethyldihydrothebainol (II,  $R = R' = Me$ ).** A solution of 7-acetyl-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethyldihydrothebainol (V,  $R' = Me$ ) (3.79 g) in dry ether (50 ml) was added to a vigorously stirred boiling solution of methylmagnesium chloride (from 0.96 g of magnesium and 5.64 g of methyl iodide) in ether (150 ml). The mixture was heated under reflux for 3 hr, poured into saturated ammonium chloride solution. The ether was separated, dried, and evaporated, to leave a viscous residue (3.8 g) that crystallized on standing. Recrystallization of the residue from methanol afforded the tertiary alcohol II ( $R = R' = Me$ ) as white prisms, mp 140°.

*Anal.* Calcd for  $C_{24}H_{32}NO_4$ : C, 73.0; H, 8.0. Found: C, 72.8; H, 7.8.

**5,14-Ethano-18-isopropylidene-4-O-methylthebainone (III,  $R = Me$ ,  $R' = H$ ).** 5,7-Dehydro-6,14-endo-etheno-7-(1-hydroxy-1-methylethyl)-4,6-O-dimethyldihydrothebainol (II,  $R = R' = Me$ ) was dissolved in 2 *N* hydrochloric acid (10 ml) and after 5 min the solution was basified with ammonia, and the precipitated solid collected. After recrystallization from methanol the unsaturated ketone III ( $R = R' = Me$ ) was obtained as off-white crystals, mp 178°,  $\nu_{max}$  1690 cm<sup>-1</sup>, identical in melting point, mixture melting point, and infrared absorption with the 4-O-methyl ether base III ( $R = Me$ ,  $R' = H$ ) obtained by the acid-catalyzed rearrangement of the alcohol XIII ( $R = Me$ ).<sup>11</sup>

*Anal.* Calcd for  $C_{24}H_{30}NO_4$ : C, 75.9; H, 7.7. Found: C, 75.8; H, 8.1.

**5,14-Ethano-4-O-methyl-18-pent-2'-ylidenethebainone (III,  $R = n-Pr$ ,  $R' = Me$ ).** 7-Acetyl-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethyldihydrothebainol (V,  $R' = Me$ ) (3.8 g) was treated with *n*-propylmagnesium chloride, and the noncrystalline reaction product was dissolved in 2 *N* hydrochloric acid. Basification of the acid solution with ammonia, isolation of the product by ether extraction, and crystallization from aqueous methanol afforded the unsaturated ketone III ( $R = n-Pr$ ,  $R' = Me$ ) as prisms, mp 70°,  $\nu_{max}$  1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{25}H_{32}NO_4 \cdot 0.5H_2O$ : C, 75.0; H, 8.2. Found: C, 74.9; H, 8.1.

**5,14-Ethano-4-O-methyl-18-(1'-methyl-2'-phenylethylidene)thebainone (III,  $R = CH_2Ph$ ,  $R' = Me$ ).** This was prepared by the acid hydrolysis of the noncrystalline reaction product of the action of benzylmagnesium bromide on the ketone V ( $R' = Me$ ), and was obtained as white prisms, mp 142°,  $\nu_{max}$  1690 cm<sup>-1</sup>, from 70% ethanol.

*Anal.* Calcd for  $C_{26}H_{30}NO_4 \cdot H_2O$ : C, 76.1; H, 7.4. Found: C, 76.3; H, 7.6.

**5,14-Ethano-18-(1'-cyclohexylethylidene)-4-O-methylthebainone (III,  $R = cyclohexyl$ ,  $R' = Me$ ).** This was obtained by the acid hydrolysis of the noncrystalline product of the reaction between cyclohexylmagnesium chloride and the ketone V ( $R' = Me$ ), and was recovered as white prisms, mp 98°,  $\nu_{max}$  1690 cm<sup>-1</sup>, from ethanol.

*Anal.* Calcd for  $C_{26}H_{34}NO_4$ : C, 77.8; H, 8.3. Found: C, 77.4; H, 8.0.

**5,14-Ethano-18-isopropylidene-4-O-methylthebainone Methine (XXI).** 5,14-Ethano-18-isopropylidene-4-O-methylthebainone (9 g) and methyl iodide (60 ml) were boiled together under reflux for 3 days with stirring. The solid matter (12 g) was collected, when the methiodide was obtained as almost colorless prisms, mp 236°, from ethanol.

*Anal.* Calcd for  $C_{24}H_{28}NO_4 \cdot CH_3I$ : C, 57.6; H, 6.2. Found: C, 57.4; H, 6.4.

The methiodide (12 g) in water (100 ml) was boiled with potassium hydroxide (15 g) for 10 min. The mixture was cooled and the solid was collected (8.7 g) and recrystallized from benzene-petroleum ether (bp 60–80°), when the methine base was obtained as elongated white prisms, mp 152°,  $\nu_{max}$  1690 cm<sup>-1</sup>,  $\lambda_{max}$  272 and 305 m $\mu$ ,  $\epsilon_{max}$  12,600 and 47,200.

*Anal.* Calcd for  $C_{24}H_{28}NO_4$ : C, 76.3; H, 7.9. Found: C, 76.8; H, 8.1.

The methine methiodide formed rapidly from the base and methyl iodide in benzene, and was obtained from methanol as white prisms, mp 180°.

*Anal.* Calcd for  $C_{24}H_{28}NO_4 \cdot CH_3I$ : C, 58.3; H, 6.4. Found: C, 58.4; H, 6.4.

This methiodide resisted Hofmann degradation in aqueous solution, and pyrolysis of the methohydroxide resulted in the loss of methanol and the production of the methine base in very high yield. Only a trace of uncharacterized neutral matter was obtained.

**18-Acetyl-5,14-ethano-4-O-methylthebainone Methine (XXII).** 18-Acetyl-5,14-ethano-4-O-methylthebainone methiodide (see above) (4.0 g) was boiled with water (100 ml) and potassium hydroxide (15 g) for 10 min. The precipitated oil was isolated by ether extraction, and the uncrystallizable product was converted into its hydrochloride, which was obtained as white prisms, mp 210°, from ethanol-ether;  $\nu_{max}$  1690 cm<sup>-1</sup>;  $\lambda_{max}$  272, 298, and 308 m $\mu$ ;  $\epsilon_{max}$  10,000, 4800, and 4000.

*Anal.* Calcd for  $C_{24}H_{28}NO_4 \cdot HCl \cdot H_2O$ : C, 64.2; H, 7.2. Found: C, 64.2; H, 7.4.

The methine methiodide, prepared from the methine base in benzene, was obtained from ethanol as white prisms, mp 283°.

*Anal.* Calcd for  $C_{24}H_{28}NO_4 \cdot CH_3I$ : C, 55.9; H, 6.0. Found: C, 55.5; H, 6.0.

**18-Acetyl-5,14-ethano-7,8,9,10-tetrahydrothebenone (XXIII).** 18-Acetyl-5,14-ethano-4-O-methylthebainone methine methiodide (0.20 g) in water (10 ml) was boiled under reflux with potassium hydroxide (1.5 g) for 6 hr. The insoluble brown product (0.031 g) was dissolved in benzene, and the solution was passed through a short column of alumina, which removed a trace of a violet impurity. The almost colorless solid recovered from the eluate (one spot on thin layer chromatography) was recrystallized from petroleum ether (bp 60–80°), when the ketone XXIII was obtained as white prisms, mp 167–168°,  $\nu_{max}$  1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{30}O_4$ : C, 75.0; H, 6.0. Found: C, 74.7; H, 6.3.

**5,14-Ethano-6,18-(2'-oxoethano)thebainol (XXV).** Potassium hydroxide (1 g) in water (10 ml) was added to a solution of 18-acetyl-5,14-ethanothebainone (VII,  $R' = H$ ) (5 g) in 2-ethoxyethanol (80

ml), and the solution was heated in the boiling water bath for 5 min. Water was then added (100 ml), and a pale yellow solution was obtained. The addition of saturated ammonium chloride solution (20 ml) discharged the yellow color. Almost immediately a crystalline solid began to separate, and the separation was complete after 10 min. The solid was collected, washed with water, and recrystallized from 2-ethoxyethanol, when the base XXV was obtained as white prisms, mp 275–276°,  $\nu_{\max}$  1740  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{22}\text{H}_{31}\text{NO}_4$ : C, 71.9; H, 6.8. Found: C, 71.8; H, 6.8.

The same base was obtained on warming the diketone VII ( $\text{R}' = \text{H}$ ) in aqueous potassium hydroxide containing sufficient ethanol to prevent the separation of the potassium salt. Dilution of the solution with water and addition of ammonium chloride gave an immediate precipitate which, on collection and recrystallization from aqueous 2-ethoxyethanol, afforded the base XXV as prisms, mp 275–276°,  $\nu_{\max}$  1740  $\text{cm}^{-1}$ .

The methiodide, prepared from the base and methyl iodide in 2-ethoxyethanol solution under reflux for 5 hr, was obtained as elongated prisms, mp 268–270°, from water.

*Anal.* Calcd for  $\text{C}_{22}\text{H}_{31}\text{NO}_4 \cdot \text{CH}_3\text{I} \cdot \text{H}_2\text{O}$ : C, 52.3; H, 5.7. Found: C, 52.0; H, 5.9.

**5,14-Ethano-6,18-(2'-oxoethano)thebainol Methine (XXIV).** a. 18-Acetyl-5,14-ethanothebainone methiodide (4.5 g) was boiled with water (60 ml) and potassium hydroxide (15 g) for 30 min. The solution was cooled and the liquid decanted from the glassy solid, which was dissolved in water, and the solution was acidified with dilute hydrochloric acid. On basification of the solution with ammonia, no precipitate was obtained, and the base was isolated by extraction with chloroform, when it was obtained as a yellow solid. On recrystallization from methanol it was recovered as white prisms, mp 204°,  $\nu_{\max}$  1740  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{21}\text{H}_{27}\text{NO}_4$ : C, 72.4; H, 7.1. Found: C, 72.6; H, 7.4.

b. The same base was obtained in the same way from 5,14-ethano-6,18-(2'-oxoethano)thebainol methiodide.

**5,7-Dehydro-6,14-endo-etheno-7-ethoxycarbonyl-6-O-methyldihydrothebainol (X, R = Et, R' = H).** 6,14-endo-Etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (I,  $\text{CH}_2 = \text{OEt}$ ) (15 g) in dry *t*-butyl alcohol (100 ml) was added to a solution of potassium (6 g) in *t*-butyl alcohol (150 ml), and the mixture was boiled under reflux for 15 min. The resulting solution was cooled and poured into an excess of saturated aqueous ammonium chloride, and the organic layer was separated, concentrated under reduced pressure, and kept in the refrigerator overnight. The crystalline ester that separated was collected (14 g) and recrystallized from methanol, when it was obtained as white prisms, mp 186°,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{33}\text{NO}_5 \cdot \text{H}_2\text{O}$ : C, 67.2; H, 7.2. Found: C, 67.1; H, 7.0.

The same base was obtained during the reaction of 6,14-endo-etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine with Grignard reagents other than methylmagnesium iodide. Being phenolic it was readily separated by virtue of its solubility in aqueous alkalis from the tertiary carbinols resulting from normal Grignard attack of the ester. The phenolic material so obtained, however, contained some tertiary alcohol II ( $\text{CH}_2 = \text{R}$ ), which was removed by acid-catalyzed hydrolysis in cold 2 *N* hydrochloric acid (in which the ester is stable) to the sparingly soluble hydrochloride of the related ketone III ( $\text{CH}_2 = \text{R}$ ). In this way the ester X ( $\text{R} = \text{Et}$ ,  $\text{R}' = \text{H}$ ) was obtained from the reaction of the ester I ( $\text{CH}_2 = \text{OEt}$ ) and ethylmagnesium bromide and *n*-propylmagnesium chloride, together with the hydrochlorides of 5,14-ethano-18-pent-3'-ylidenethebainone (III,  $\text{R}' = \text{H}$ ,  $\text{CH}_2 = \text{R} = \text{Et}$ ), mp 285–287°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$  (*Anal.* Calcd for  $\text{C}_{24}\text{H}_{33}\text{NO}_5 \cdot \text{HCl}$ : C, 69.8; H, 7.4. Found: C, 70.0; H, 7.3) and 5,14-ethano-18-hept-4'-ylidenethebainone (III,  $\text{R}' = \text{H}$ ,  $\text{CH}_2 = \text{R} = n\text{-Pr}$ ), mp 291°,  $\nu_{\max}$  1690  $\text{cm}^{-1}$  (*Anal.* Calcd for  $\text{C}_{27}\text{H}_{35}\text{NO}_5 \cdot \text{HCl}$ : C, 70.8; H, 7.9. Found: C, 70.6; H, 8.0).

**5,7-Dehydro-6,14-endo-etheno-7-ethoxycarbonyl-4,6-O-dimethyldihydrothebainol (X, R = Et, R' = Me).** 6,14-endo-Etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (I,  $\text{CH}_2 = \text{OEt}$ ) (10 g) was heated with a solution of potassium (4 g) in dry *t*-butyl alcohol (150 ml) under reflux for 15 min, and methyl iodide (8 ml) in *t*-butyl alcohol (20 ml) was then added slowly with vigorous stirring. The mixture was filtered from precipitated potassium iodide and evaporated, leaving a semisolid residue, which was extracted thoroughly with ether. Evaporation of the ether extract afforded a viscous gum, which was crystallized with difficulty from aqueous methanol, when the ester X ( $\text{R} = \text{Et}$ ,  $\text{R}' = \text{Me}$ ) was obtained as white prisms, mp 100°,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{33}\text{NO}_5$ : C, 70.6; H, 7.3. Found: C, 70.2; H, 7.1.

**5,7-Dehydro-6,14-endo-etheno-7-isopropoxycarbonyl-6-O-methyldihydrothebainol (X, R = *i*-Pr, R' = H).** A solution of 6,14-endo-etheno-7 $\alpha$ -ethoxycarbonyltetrahydrothebaine (10 g) in dry benzene was added to one of sodium (1 g) in 2-propanol (10 ml). The resulting mixture was boiled under reflux for 3 hr, with a Whitmore-Lux variable take-off head so adjusted that one drop in 12 of the refluxing liquid was removed. The resulting mixture was poured into an excess of ice-cold 2 *N* hydrochloric acid; the aqueous layer was removed and made alkaline with ammonia. The base precipitated in this way was collected and recrystallized from aqueous 2-ethoxyethanol, when the isopropyl ester was obtained as white prisms, mp 177–178°,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{33}\text{NO}_5$ : C, 70.6; H, 7.3. Found: C, 70.5; H, 7.3.

The ester was soluble in alkalis and the solution coupled readily with diazotized sulfanilic acid to give a blood red solution.

The following esters were prepared by base-catalyzed rearrangement of the ester I ( $\text{CH}_2 = \text{OEt}$ ), with simultaneous base-catalyzed ester exchange: 5,7-dehydro-6,14-endo-etheno-6-O-methyl-7-propoxycarbonyl dihydrothebainol (X, R = *n*-Pr, R' = H, white prisms, mp 137°, from methanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{24}\text{H}_{33}\text{NO}_5$ : C, 70.6; H, 7.3. Found: C, 70.5; H, 7.3); 5,7-dehydro-6,14-endo-etheno-7-isobutoxycarbonyl-6-O-methyldihydrothebainol (X, R = *i*-Bu, R' = H, white prisms, mp 84°, from aqueous methanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{26}\text{H}_{35}\text{NO}_5 \cdot 0.5\text{H}_2\text{O}$ : C, 69.6; H, 7.6. Found: C, 69.2; H, 7.8); 7-butoxycarbonyl-5,7-dehydro-6,14-endo-etheno-6-O-methyldihydrothebainol (X, R = *n*-Bu, R' = H, white prisms, mp 138°, from aqueous methanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{28}\text{H}_{37}\text{NO}_5$ : C, 71.0; H, 7.5. Found: C, 70.5; H, 7.3); 5,7-dehydro-6,14-endo-etheno-6-O-methyl-7-pentyloxycarbonyldihydrothebainol (X, R = *n*-Am, R' = H, white prisms, mp 146°, from methanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{29}\text{H}_{39}\text{NO}_5$ : C, 71.5; H, 7.7. Found: C, 71.0; H, 7.9); 5,7-dehydro-6,14-endo-etheno-7-furfuryloxycarbonyl-6-O-methyldihydrothebainol (X, R = furfuryl, R' = H, white prisms, mp 211°, from ethanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{27}\text{H}_{33}\text{NO}_6$ : C, 70.0; H, 6.3. Found: C, 69.6; H, 6.2); 5,7-dehydro-6,14-endo-etheno-6-O-methyl-7-tetrahydrofurfuryloxycarbonyldihydrothebainol (X, R = tetrahydrofurfuryl, R' = H, noncrystalline, hydrochloride white prisms, mp 236°, from ethanol. *Anal.* Calcd for  $\text{C}_{28}\text{H}_{35}\text{NO}_6 \cdot \text{HCl}$ : C, 64.1; H, 6.8. Found: C, 63.6; H, 7.1); 7-cyclohexyloxycarbonyl-5,7-dehydro-6,14-endo-6-O-methyldihydrothebainol (X, R = cyclohexyl, R' = H, white prisms, mp 200°, from ethanol,  $\nu_{\max}$  1715  $\text{cm}^{-1}$ . *Anal.* Calcd for  $\text{C}_{28}\text{H}_{35}\text{NO}_6$ : C, 72.3; H, 7.5. **5,14-Ethano-18-ethoxycarbonylthebainone (XI, R = COOEt, R' = H).** 5,7-Dehydro-6,14-endo-etheno-7-ethoxycarbonyl-6-O-methyldihydrothebainol (X, R = Et, R' = H) (2 g) was heated with 2 *N* hydrochloric acid (20 ml) at 100° for 5 min. The solution was basified with ammonia, and the precipitated base was isolated by ether extraction and crystallized from methanol, when the ester XI (R = COOEt, R' = H) (1.7 g) was obtained as white prisms, mp 168°,  $\nu_{\max}$  1735 and 1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $\text{C}_{24}\text{H}_{31}\text{NO}_6$ : C, 69.5; H, 6.8. Found: C, 69.6; H, 6.7.

**5,14-Ethano-18-ethoxycarbonyl-4-O-methylthebainone (XI, R = COOEt, R' = Me).** Hydrolysis of the ester X (R = Et, R' = H) with 2 *N* hydrochloric acid at 100° for 5 min, followed by basification of the solution with ammonia, afforded the ester XI (R = COOEt, R' = Me), which was isolated by ether extraction and obtained from aqueous methanol with difficulty as white prisms, mp 78°,  $\nu_{\max}$  1735 and 1690  $\text{cm}^{-1}$ .

*Anal.* Calcd for  $C_{24}H_{23}NO_4$ : C, 70.0; H, 7.1. Found: C, 69.5; H, 7.0.

**5,14-Ethano-18-(2'-ethoxyethoxycarbonyl)thebaine (XI, R = COOCH<sub>2</sub>CH<sub>2</sub>OEt, R' = H)** was obtained as above by the hydrolysis of the ester X (R = CH<sub>2</sub>CH<sub>2</sub>OEt, R' = H) with 2 *N* hydrochloric acid at 100° for 5 min. The base could not be crystallized, but the hydrochloride was obtained from ethanol-ether as white prisms, mp 254–256°,  $\nu_{\max}$  1735 and 1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{23}NO_4 \cdot HCl$ : C, 62.7; H, 6.9. Found: C, 62.6; H, 6.8.

**7-Cyano-5,7-dehydro-6,14-endo-etheno-6-O-methyldihydrothebaine (XII, R' = H).** 7-Cyano-6,14-endo-ethenotetrahydrothebaine (10 g, mixture of 7 $\alpha$  and 7 $\beta$  isomers obtained directly from the Diels-Alder addition of acrylonitrile to thebaine<sup>9</sup>) in ether (200 ml) was added to a boiling solution of methylmagnesium iodide (from 2.52 g of magnesium and 15.4 g of methyl iodide) in ether (100 ml), and the mixture was heated and stirred under reflux for 4 hr, and then poured into aqueous ammonium chloride. The ether layer was separated, dried, and evaporated, and the crystalline residue (9.3 g) was recrystallized from methanol, when the nitrile XII (R' = H) was obtained as almost white prisms, mp 234°,  $\nu_{\max}$  2250 cm<sup>-1</sup>, readily soluble in aqueous potassium hydroxide and coupling in solution with diazotized sulfanilic acid to give a red dye.

*Anal.* Calcd for  $C_{22}H_{21}N_2O_2$ : C, 72.5; H, 6.7. Found: C, 72.8; H, 6.8.

The same base was obtained when 7-cyano-6,14-endo-ethenotetrahydrothebaine (10 g) was added to a solution of potassium (5 g) in *t*-butyl alcohol (200 ml), the solution being maintained at 65° for 15 min after which it was poured into saturated aqueous ammonium chloride, and the product was isolated by ether extraction. It was obtained also by either process starting from the pure 7 $\alpha$  and 7 $\beta$  nitriles.

**7-Cyano-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethyldihydrothebaine (XII, R' = Me).** 7-Cyano-6,14-endo-ethenotetrahydrothebaine (6 g, mixture of 7 $\alpha$  and 7 $\beta$  forms) was added to a solution of potassium (2.4 g) in *t*-butyl alcohol (40 ml) and methyl iodide (6 ml) was added to the resulting red solution. The mixture was stirred at ca. 65° for 1 hr and poured into aqueous ammonium chloride, and the organic layer was separated. The aqueous layer was extracted once with ether, and the combined organic solutions were evaporated to dryness. The residue (6 g) was recrystallized from methanol, when the O-methyl ether XII (R' = Me) (5 g) was obtained as prisms, mp 187°,  $\nu_{\max}$  2250 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{25}N_2O_2$ : C, 73.0; H, 6.9. Found: C, 72.6; H, 6.9.

**7-Cyano-5,7-dehydro-6,14-endo-etheno-4-O-ethyl-6-O-methyldihydrothebaine (XII, R = Et).** 7-Cyano-6,14-endo-ethenotetrahydrothebaine (3 g) in a solution of potassium (1.2 g) in *t*-butyl alcohol (20 ml) at 60° was ethylated by the addition of ethyl bromide (3 ml). Isolation of the product in the manner described above gave the 4-O-ethyl ether XII (R' = Et) as white needles, mp 120°, from aqueous methanol.

*Anal.* Calcd for  $C_{26}H_{27}N_2O_2$ : C, 73.5; H, 7.15. Found: C, 73.0; H, 7.3.

**4-O-Acetyl-7-cyano-5,7-dehydro-6,14-endo-etheno-6-O-methyldihydrothebaine (XII, R<sup>1</sup> = COCH<sub>3</sub>).** Acetyl chloride (3 ml) was added to a solution of 7-cyano-6,14-endo-ethenotetrahydrothebaine (3 g) in one of potassium (1.2 g) in *t*-butyl alcohol (30 ml). After 15 min at room temperature the mixture was poured into ammonium chloride solution containing ammonia. The product

was isolated by ether extraction and recrystallized from methanol, when the acetylated nitrile XII (R' = COCH<sub>3</sub>) was obtained as elongated plates, mp 217°,  $\nu_{\max}$  2250 and 1720 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{23}N_2O_4$ : C, 70.9; H, 6.4. Found: C, 70.9; H, 6.4.

**18-Cyano-5,14-ethanothebaine (XI, R = CN, R' = H).** 7-Cyano-5,7-dehydro-6,14-endo-etheno-6-O-methyldihydrothebaine (XII, R' = H) (5 g) was heated for 5 min at 100° with 2 *N* hydrochloric acid (20 ml). The ketone was precipitated with ammonia and recrystallized from methanol, when it was obtained as white prisms, mp 200°,  $\nu_{\max}$  2250 and 1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{21}H_{19}N_3O_2$ : C, 72.0; H, 6.3. Found: C, 72.1; H, 6.2.

**18-Cyano-5,14-ethano-4-O-methylthebaine (XI, R = CN, R' = Me).** Prepared as above by the hydrolysis of the methylated nitrile XII (R' = Me), this ketone was obtained as prisms, mp 284°,  $\nu_{\max}$  2250 and 1690 cm<sup>-1</sup>, from ethanol.

*Anal.* Calcd for  $C_{22}H_{21}N_3O_2$ : C, 72.5; H, 6.7. Found: C, 72.1; H, 6.3.

**18-Cyano-5,14-ethano-4-O-ethyl-6-O-methylthebaine (XI, R' = Et)** was obtained by the hydrolysis of the nitrile XII (R' = Et) with 2 *N* hydrochloric acid at 100° as above, and was recovered from aqueous methanol as prisms, mp 200°,  $\nu_{\max}$  2250 and 1690 cm<sup>-1</sup>.

*Anal.* Calcd for  $C_{24}H_{25}N_3O_2 \cdot H_2O$ : C, 69.7; H, 7.1. Found: C, 69.9; H, 6.7.

**Reaction of the Nitrile XII (R' = Me) with Methylmagnesium Iodide.** 7-Cyano-5,7-dehydro-6,14-endo-etheno-4,6-O-dimethyldihydrothebaine (XII, R' = Me) (6.1 g) in tetrahydrofuran (200 ml) was added to a boiling stirred solution of methylmagnesium iodide (from 2 g of magnesium and 4.6 ml of methyl iodide) in tetrahydrofuran (100 ml). The resulting mixture was stirred and heated under reflux for 5 hr, and poured into saturated ammonium chloride solution. The organic layer was separated, and the aqueous layer was extracted once with ether. Evaporation of the combined organic solutions afforded a viscous material, which was warmed on the water bath for 30 min with 2 *N* hydrochloric acid (25 ml). Basification of the solution with ammonia and isolation of the product by ether extraction afforded a solid (4 g). On crystallization from ethanol this gave 18-acetyl-5,14-ethano-4-O-methylthebaine (VII, R' = Me), mp 186°, identical in melting point, mixture melting point, and infrared absorption with the base obtained by the methylation of the phenol VII (R<sup>1</sup> = H).

**Action of Boron Tribromide on the Ketone I.** 7 $\alpha$ -Acetyl-6,14-endo-ethenotetrahydrothebaine (5 g) in methylene chloride (30 ml) was treated with boron tribromide (3.2 g) at 5° for 1 hr. Aqueous ammonium chloride containing ammonia was added to the solution, and the organic layer was separated, dried, and evaporated, when 18-acetyl-5,14-ethanothebaine, mp 199–200°, alone or mixed with an authentic specimen was obtained.

**Abstract:** Nuclear magnetic spectroscopy, including homonuclear field-sweep spin-decoupling techniques, has been used to determine the stereochemistry of the epimers and the configuration of some of the diastereomers formed by the Diels–Alder addition of electrophilic olefins to thebaine, followed by further transformations. Analyses of the nmr spectra include the comparisons of computed spectra with the observed spectra for the various spin–spin systems. Differences in chemical shift between similar protons in the various compounds have been explained in terms of the anisotropy of a phenyl substituent or the shielding parameters of the cyclic tertiary nitrogen atom and the bicyclo[2.2.2]octene double bond present in these structures.

The preceding papers<sup>2</sup> describe the preparation and chemical transformations of a variety of 6,14-*endo*-ethenotetrahydrothebaine derivatives containing the bicyclo[2.2.2]octene system, obtained by Diels–Alder addition of electrophilic olefins to thebaine followed by further transformations. This paper describes the application of nuclear magnetic resonance (nmr) spectroscopy, including homonuclear field-sweep spin-decoupling techniques, to the elucidation of the absolute configuration of asymmetric centers formed during these transformations. Included specifically are stereochemical assignments of epimers (at C-7) produced by the Diels–Alder reactions<sup>2a</sup> (and generally maintained during subsequent transformations) and a study of diastereomeric alcohols (at C-19) formed by stereoselective transformations of the Diels–Alder adducts.<sup>2b</sup> The structure below is a stereochemical representation

## Compounds Epimeric at C-7

A mixture of 7-cyano epimers (Ia and Ib) was obtained by repeating the synthesis of Bentley and Ball,<sup>4</sup> and these isomers were separated and isolated in approximately equal amounts by a combination of fractional crystallization and partition chromatography.<sup>2b</sup> At the outset, chemical data did not permit unequivocal assignment of the C-7 epimer configuration. However, the nmr data, including the results of spin decoupling, demonstrated that the more polar isomer, mp 183–184°, had the 7α-nitrile configuration (Ia) with the 6,14-etheno bridge disposed in the *endo* position “inside” the tetrahydrothebaine skeleton. The nmr spectrum of this epimer is shown in Figure 1 (with arrows indicating the spin systems established by decoupling experiments). Irradiation of the olefinic H-18 (δ 5.93) established that it was part of a four-spin system. Spin coupling was found between H-18 and H-17 (δ 5.61),  $J_{17,18} = 9.0$  cps (a typical AB pattern). Additionally, H-18 was coupled to both H-5β (δ 4.50),  $J_{5,18} = ca. 2$  cps, and to H-7β (δ 2.85),  $J_{7,18} < 1.0$  cps. Examination of a Dreiding model of Ia showed that both H-5β and H-7β, together with H-18 and the intervening carbon atoms, approximate a plane in which the connecting bonds resemble a “W”;<sup>5</sup> both protons would therefore be expected to couple with H-18.<sup>6</sup> These couplings are summarized in Figure 1. Decoupling experiments were also performed on the four-line pattern of the upfield proton (δ 1.50). This absorption, eventually assigned to H-8α, was established as part of a *three-spin* system involving H-7β and H-8β. Inspection of the H-8α pattern at δ 1.50 established that  $J_{8α,8β} = 12.0$  cps (geminal coupling) and  $J_{7β,8α} = 4.5$  cps (vicinal coupling, transoid). By using spin decoupling and observing the

Figure 1. Proton nmr spectrum of the 7 $\alpha$ -cyano epimer Ia.

perturbations of the four-line H-8 $\alpha$  pattern, it was possible to locate both of the H-7 $\beta$  and H-8 $\beta$  multiplets in the region  $\delta$  2.5–3.5. However, owing to resonances from other protons in this region (H-9 $\alpha$  and H-10 $\beta$ ), identification of the individual resonance lines from these protons was difficult. Careful examination of the  $\delta$  2.8 region revealed a pair of doublets which had the same 4.5-cps vicinal splitting, but separated by 9.5 cps ( $J_{7\beta,8\beta}$ ) in which the intensities of each component varied considerably. Careful spin decoupling then clearly indicated that the 4.5-cps doublets of H-8 $\alpha$  were collapsed by irradiating these doublets at  $\delta$  2.8, and, moreover, it appeared that the upfield doublet of H-8 $\alpha$  was collapsed by irradiating the *low-field* doublet of the pair at  $\delta$  2.8, and *vice versa*. This indicated that the two couplings,  $J = 12.0$  cps and  $J = 9.5$  cps, had opposite signs. This finding was consistent with the assigned arrangement of these protons, for it is known that the sign of  $J_{HH}$  (geminal) is negative while that for  $J_{HH}$  (vicinal) is positive.<sup>7</sup> Accordingly, the  $\delta$  2.8 doublets belonged to H-7 $\beta$ , and the H-8 $\beta$  pattern appeared partly hidden near  $\delta$  3.2.

To confirm the observed intensities of the H-7 $\beta$  doublets and to help locate the H-8 $\beta$  pattern, the expected spectrum was calculated using estimated chemical shifts (which approximated the true values) and the following  $J$  values:  $J_{8\alpha,8\beta} = -12.0$  cps,  $J_{7\beta,8\beta} = +9.5$  cps, and  $J_{7\beta,8\alpha} = +4.5$  cps. The three spins were treated as an ABC system, following established mathematical procedures.<sup>8,9</sup> The line positions and intensities were calculated with the aid of a program written for a Burroughs 205 computer. The excellent agreement between the calculated and experimental spectra is shown in Figure 2, where the calculated H-8 $\beta$  set of lines fits under the observed lines. Two of the H-8 $\beta$  lines can be seen in the spectrum, while the other two are obscured. The three combination lines which result from an ABC treatment are omitted, as their

Figure 2. Calculated and experimental spectra (nmr) for the C-7 $\beta$ , C-8 $\alpha$ , C-8 $\beta$ , C-9 $\alpha$ , C-10 $\alpha$ , and C-10 $\beta$  protons in the 7 $\alpha$ -cyano epimer Ia.

intensities were near zero. The patterns for the H-9 $\alpha$  and H-10 $\beta$  protons were also found in this region ( $\delta$  2.5–3.5) which integrates for four protons (H-7 $\beta$ ,  $\delta$  2.8 and H-8 $\beta$ ,  $\delta$  3.2 are also present). Using estimated chemical shifts for H-9 $\alpha$  ( $\delta$  3.20), H-10 $\beta$  ( $\delta$  3.20), and H-10 $\alpha$  ( $\delta$  2.43) with the observed coupling constants ( $J_{8\alpha,10\alpha} = +6.2$  cps,  $J_{10\alpha,10\beta} = -18.0$  cps, and  $J_{8\alpha,10\beta} = ca. 0.0$  cps, which are in agreement with Rüll and Gagnaire<sup>10</sup>) the line positions and intensities of these proton patterns were calculated, and the agreement between these calculated and observed spectra is also shown in Figure 2. Thus, spin decoupling, together with the excellent agreement between the computed and observed spectra, confirmed the chemical shifts assigned for H-7 $\beta$  ( $\delta$  2.85) and H-8 $\beta$  ( $\delta$  3.25), as indicated in Figures 1 and 2, even though the complex patterns resulting from H-9 $\alpha$  and H-10 $\beta$  resonance lines also appeared in this region.

Very small (<0.2 cps) long-range coupling between H-8 $\beta$  ( $\delta$  3.25) and H-17 ( $\delta$  5.61) was also detected by spin decoupling. These protons are sterically related to each other in the same sense that H-7 $\beta$  is related to

Figure 3. Proton nmr spectrum of the 7 $\beta$ -cyano epimer Ib.

H-18 (see structures I–X). The downfield chemical shift of H-8 $\beta$  ( $\delta$  3.25) compared with that of H-8 $\alpha$  ( $\delta$  1.50) was somewhat surprising, since the corresponding protons in bicyclo[2.2.2]octene resonate at  $\delta$  1.50 and 1.27, respectively.<sup>6c</sup> The large difference in chemical shifts of the geminal protons H-8 $\alpha$  and H-8 $\beta$  may be understandable upon consideration of the shielding (or the free electron pair) of the tertiary nitrogen atom held in proximity to H-8 $\beta$  (ca. 2.9 Å)<sup>11</sup> by the rigid ring system (see structures I–X). The chemical shift of H-8 $\beta$  is similar to that observed for the *syn*-methylene bridge proton of sparteine,<sup>12</sup> which is also held in the proximity of a nitrogen atom (ca. 2.3 Å away). Additional discussion of this point is included in the latter part of this paper, as this marked downfield shift for H-8 $\beta$  is evident in virtually all of the compounds examined in this series.

Assignment of the other isomer, mp 195–196°, as the 7 $\beta$ -cyano epimer (Ib) was based on equivalent decoupling experiments; this nmr spectrum is shown in Figure 3. In contrast to Ia, spin decoupling established that H-18 in this epimer was part of a *three-spin system*. Again, H-18 ( $\delta$  5.90) and H-17 ( $\delta$  5.57) formed a typical AB coupling pattern ( $J_{17,18}$  = 9.0 cps), and the H-5 $\beta$  ( $\delta$  4.98), H-18 coupling ( $J_{5\beta,18}$  = ca. 2 cps) was also similar to that found previously. However, no coupling was found between H-18 and any upfield proton in the area  $\delta$  2.8–3.1, where H-7 $\alpha$  and H-8 $\beta$  were subsequently located by irradiation of H-8 $\alpha$  (the upfield proton;  $\delta$  1.70 in this epimer). The absence of spin coupling between H-18 and H-7 $\alpha$  in this isomer is as expected since the 7 $\beta$  position is now occupied by the nitrile group, and H-7 $\alpha$  is not oriented correctly<sup>6</sup> for long-range coupling with H-18. The downfield shift of H-5 $\beta$  from  $\delta$  4.50 for the 7 $\alpha$ -nitrile (Ia) to  $\delta$  4.98 for this epimer (Ib) was especially noteworthy. The chemical shifts for H-5 $\beta$  in virtually all of the related compounds (including II–XIV) appear to be diagnostic for assigning the configuration at C-7, and these ranges for both series of C-7 epimers are summarized in Table I. In-

deed, mixtures of C-7 epimers (including Ia and Ib) were frequently recognized by examination of their nmr spectra (even of relatively crude products), as resonances from other protons (except for exchangeable hydroxyl protons) were generally not found in the  $\delta$  4.3–5.2 region. Confirmation of the C-7 epimer assignment based on the readily observed chemical shift for H-5 $\beta$  could then be established by spin decoupling.

Table I. Protons Diagnostic for C-7 Substituents

Proton	No. of examples	Av chem shift, $\delta$	Exceptions
			7 $\alpha$ Substituted
H-5 $\beta$	21	$4.57 \pm 0.05$	XIIIa (4.47), b (4.47), c (4.37)
			7 $\beta$ Substituted
H-5 $\beta$	3	$5.07 \pm 0.12$	
			7 $\alpha$ or 7 $\beta$ Substituted (Ia–IX)
H-8 $\alpha$	8	$1.35 \pm 0.15$	IIIa (0.79), b (?), VIII (1.18), IX (0.93)
			7 $\alpha$ -C-19 Carbinols
H-8 $\alpha$	11	$0.78 \pm 0.05$	XIb (1.20), XIIa (1.22), IIIb (?)

Close examination of the spectra and equivalent spin-decoupling experiments on the H-8 $\alpha$  four-line pattern ( $\delta$  1.70) of Ib established that this proton was still part of a *three-spin system*. The high-field H-8 $\alpha$  lines now showed nearly equal splittings of 11.2 cps (vicinal) and 12.2 cps (geminal). This increase in vicinal coupling would be expected for the *cis* relationship between H-7 $\alpha$  and H-8 $\alpha$ . Some of the H-7 $\alpha$  and H-8 $\beta$  lines (in the  $\delta$  2.5–3.5 region) of this 7 $\beta$  epimer (see Figure 3) were more obvious than the corresponding lines in the spectrum of the 7 $\alpha$  epimer (see Figure 1). This ABC system (H-8 $\beta$ , H-7 $\alpha$ , H-8 $\alpha$ ) may be approximated by an ABX pattern where the AB part consists of two AB subspectra. One of these slightly perturbed AB subspectra was visible near  $\delta$  2.9 (Figure 3). The location of the other AB subspectrum followed from the couplings already determined; three of the four lines were identified near  $\delta$  3.1. The third coupling (3.6

IIb	4.98	2.69	...	1.40	3.04	5.48	6.04	5 $\beta$ ,18 (<2.0), 7 $\alpha$ ,8 $\alpha$ (+13.9), 8 $\alpha$ ,8 $\beta$ (-15.6), 7 $\alpha$ ,8 $\beta$ (+5.0), 17,18 (9.0)

<sup>a</sup> General characteristics are in Table III. <sup>b</sup> These values are included in the averages in Table I.

ps) was evident by the splitting of the outer lines of each AB pattern. Using these chemical shifts and coupling constants and a negative value for the geminal coupling constant (-12.2 cps), the complete spectrum was calculated as before. By analogy with the 7 $\alpha$  epimer (Ia), the four lines belonging to the upfield halves of each AB spectrum were assigned to H-7 $\alpha$  ( $\delta$  2.79), and the low-field halves to H-8 $\beta$  ( $\delta$  3.10). The agreement with the observed spectrum is shown in Figure 4 together with equivalent results for the H-9 $\alpha$ , H-10 $\alpha$ , and H-10 $\beta$  patterns. The very small long-range coupling ( $J$  = 0.2 ps) between H-17 and H-8 $\beta$  was also detected in this epimer by spin decoupling (analogous to that observed in Ia).

These nmr data pertaining to Ia and b, including the experimentally observed spin systems and coupling constants, and consideration of the anisotropic effects of the *l*-nitrogen on the C-8 protons independently confirm the conclusions of Bentley and co-workers<sup>2a,4</sup> that neither Ia nor Ib could be an 8-cyano derivative. They also confirm the assignment of the *endo* disposition of the 6,14-etheno bridge "inside" the tetrahydrothebaine system.<sup>13</sup> These conclusions, based upon nmr data, can generally be extended to other analogous Diels-Alder adducts (e.g., IIa and IIb below), although our investigations of spin-spin couplings by double irradiation techniques (see Table II) and computed spectra produced the most definitive results with Ia and b of the several pairs of epimers studied. Other characteristic proton patterns recognized in the nmr spectra of Ia and b (and of II-XIV) are summarized in Table III.

The epimeric methyl ketones IIa and IIb<sup>14</sup> were similarly studied. The general characteristics of these nmr spectra were similar to those of the nitriles Ia and Ib (Table III). Detailed spin-decoupling experiments were also carried out to establish the appropriate spin systems for H-5 $\beta$ , H-7 $\alpha$ , H-7 $\beta$ , H-8 $\alpha$ , H-8 $\beta$ , H-17, and H-18, as before; these chemical shifts and coupling constants are included in Table II. However, additional difficulties in spin decoupling were encountered

(13) In both 8-cyano epimers, H-18 would always be expected to be part of a *four-spin system* including H-7 $\beta$  which would have a geminal coupling constant as well. This was not observed in any compound examined. The possibility that Ib might be a 6,14-*exo*-etheno derivative may be dismissed because of the similarity of the H-17 and H-18 olefinic proton patterns to those of Ia, which had been assigned the *endo*-etheno configuration<sup>2a,4</sup> on the basis of chemical data.

(14) These epimers were obtained by repeating the synthesis of Bentley and coworkers;<sup>2a,4</sup> IIa, mp 115-118° (pure by nmr and tlc), was obtained in 80% yield (first crop), and IIb, mp 198-201°, was isolated in 38% yield by partition chromatography of the mother liquors.

owing to the greater overlap of resonance patterns (e.g., in IIa). Of particular interest was the pattern for H-8 $\alpha$  in the spectrum of IIa. This was clearly seen between  $\delta$  1.1 and 1.6 (centered at  $\delta$  1.34), but it did not resemble the four-line pattern observed for H-8 $\alpha$  in the spectra of Ia, Ib, and IIb. Instead, a five-line pattern was observed. Four of the five lines were narrow and symmetrically arranged, with the inner lines

<sup>a</sup> The nmr spectra were run on a Varian A-60 spectrometer equipped with a variable-temperature probe. Solutions were 20% (w/v) in deuteriochloroform except where noted otherwise. Tetramethylsilane was used as an internal reference, and the accuracy of the measurements is within  $\delta$  0.03 for the chemical shifts and 0.5 cps for the coupling constants. The spin-decoupling work was done on a Varian DP-60 equipped with a Varian integrator-decoupler.

experiments made while observing H-8 $\alpha$  ( $\delta$  1.34) indicated that H-7 $\beta$  and H-8 $\beta$  were both near  $\delta$  2.9. With the values  $J_{8\alpha,8\beta} = -12.0$  cps,  $J_{8\alpha,7\beta} = +4.5$  cps, and  $J_{8\beta,7\beta} = +9.5$  cps, obtained from the analogous isomer (Ia), trial three-spin spectra were computed. From these, an assignment of transitions could be made to the H-8 $\alpha$  lines and four clearly visible lines assignable to H-7 $\beta$  and H-8 $\beta$ . The entire energy-level scheme could then be drawn up and the unobserved lines filled in. An exact Castellano-Waugh<sup>16</sup> calculation was carried out using the measured shift values. The spectrum was then exactly reproduced with the following parameters: H-8 $\alpha$ ,  $\delta$  1.34; H-7 $\beta$ ,  $\delta$  2.90; H-8 $\beta$ ,  $\delta$  2.91;  $J_{8\alpha,8\beta} = -12.6$  cps;  $J_{8\alpha,7\beta} = +6.5$  cps;  $J_{8\beta,7\beta} = +9.7$  cps. The two combination lines in the H-8 $\alpha$  pattern appeared at its center, separated by about 0.01 ppm, and could easily account for the central broad line (as shown in Figure 5).

Spin decoupling of the 7 $\beta$ -acetyl epimer IIb was similar to that of the 7 $\beta$ -nitrile Ib (see Tables I and III). The spin systems determined from the spectra of both IIa and IIb also confirmed the prior C-7 assignments of Bentley, *et al.*<sup>2a,4</sup> These assignments are: the configuration at C-7, that neither isomer could be an eight-substituted derivative, and that the 6,14-etheno bridge was in an *endo* disposition.

The epimeric tertiary carbinols IIIa<sup>17</sup> and IIIb,<sup>18</sup> synthesized from IIa and IIb, respectively, were also thoroughly investigated. In the 7 $\alpha$  epimer IIIa, double-irradiation methods readily established that H-7 $\beta$  had moved upfield to  $\delta$  2.1 with respect to H-7 $\beta$  at  $\delta$  2.8 in its precursor, IIa. This upfield shift of the H-7 $\beta$  lines is as expected with the removal of the inductive and/or anisotropic effects of the 7 $\alpha$ -cyano or -acetyl group.

Observation of the spectrum showed that H-8 $\alpha$  was also upfield at  $\delta$  0.79 ( $\delta$  1.32 in IIa) with the typical four-line pattern of an ABX system. Spin-decoupling experiments on this epimer gave completely analogous results to those obtained previously with Ia and IIa. The H-5 $\beta$  doublet ( $J_{5\beta,18} = ca. 2.0$  cps) was found at  $\delta$  4.50, as expected for a 7 $\alpha$  epimer, and H-18 was part of a *four-spin system*: H-5 $\beta$  ( $\delta$  4.50), H-7 $\beta$  ( $\delta$  2.10), H-17 ( $\delta$  5.43), and H-18 ( $\delta$  5.92). H-8 $\alpha$  was part of a *three-spin system*: H-8 $\alpha$  ( $\delta$  0.79), H-8 $\beta$  ( $\delta$  2.88), and H-7 $\beta$  ( $\delta$  2.10). One additional spin-decoupling experiment on IIIa established that H-1 ( $\delta$  6.50) was coupled to at least one proton (probably H-10 $\beta$ ) in the  $\delta$  3.0 region. This coupling ( $J = <0.2$  cps) was apparent in the increased line width and lowered intensity of H-1, relative to H-2 in all compounds examined.

Spin-decoupling experiments on the epimeric 7 $\beta$ -carbinol IIIb were not successful. The 8 $\alpha$  proton was not found in the region around  $\delta$  0.8 as in IIIa. This pattern was probably under the C-19-methyl resonances at *ca.*  $\delta$  1.25. Because of overlapping lines from other protons and lacking the H-8 $\alpha$  handle, it was not possible to determine the chemical shifts and coupling patterns as in the spin systems previously investigated. The 5 $\beta$  proton was observed at  $\delta$  5.26 (a peak at  $\delta$  4.58 was assigned to the C-19 OH by exchange with D<sub>2</sub>O). This was in accord with other 7 $\beta$ -substituted derivatives (Table I). Thus, although one might argue for the paramagnetic effects of the 7 $\beta$ -cyano<sup>19</sup> and -acetyl<sup>20</sup> moieties being responsible for the downfield shifts of H-5 $\beta$  in Ib and IIb (compared with Ia and IIa), these effects cannot be present in the 7 $\beta$ -carbinol IIIb, which showed an even larger downfield shift for H-5 $\beta$ . Probably steric compression is a better explanation.<sup>21</sup> It

so of interest to note that the H-8 $\alpha$  lines ( $\delta$  1.2) in had apparently moved downfield compared with position ( $\delta$  0.79) in the spectrum of IIIa even though IIIa and IIIb were C-19 tertiary carbinols (see Table I). Again, any rationale which invokes removal of the anisotropic effects of 7 $\alpha$ -cyano or -acetyl groups account for the marked upfield shift of H-8 $\alpha$  to 79 in the 7 $\alpha$ -*t*-carbinol IIIa (compared with  $\delta$  1.50 a, and  $\delta$  1.32 in IIa) apparently does not apply in equivalent changes (Ib and IIb to IIIb) for 7 $\beta$  substituents. Other factors must be involved (see Additional Studies of the C-8 Protons below).

Compounds IV–X<sup>23</sup> are additional examples of C-7 isomers whose nmr spectra were entirely analogous to those just discussed in detail (Ia–IIIb). Chemical shift data from these spectra (all 7 $\alpha$  epimers) are included in the summary data in Tables I and III. Of particular interest is the fact that the nmr spectrum ( $\delta$  4.60) of nepenthone (IV; the precursor for diastereomer XIIa) confirmed its previous assignment as a 7 $\alpha$  epimer.<sup>23,4</sup> Compounds V, VI, and VII are additional derivatives in which C-19 bears an unsaturated moiety; these spectra were similar to the spectra of Ia and IIa. Compounds VIII, IX, and X are derivatives in which C-19 is a saturated carbon bearing a hydroxyl or ether moiety; their spectra were analogous to that of IIIa.

#### Compounds Diastereomeric at C-19

In the course of our investigations, it became apparent that spectral data (nmr and infrared) might provide a basis for assigning the configuration for the asymmetric carbon at C-19 in the appropriate derivatives. This expectation was realized in our study of the diastereomeric phenylmethyl tertiary carbinols XIa–XIIa. Two other pairs of diastereomers (XIb and XIIb; XIc and XIIc) were also studied, but their spectra did not provide such definitive conclusions.

- XIa, R = C<sub>6</sub>H<sub>5</sub>  
 b, R = H  
 c, R = *n*-C<sub>3</sub>H<sub>7</sub>  
 d, R = *n*-C<sub>3</sub>H<sub>7</sub> (3-OH)  
 e, R = *i*-C<sub>3</sub>H<sub>7</sub>  
 f, R = cyclohexyl  
 g, R = CH<sub>2</sub>CH<sub>2</sub>C<sub>6</sub>H<sub>5</sub> (3-OH)

- XIIa, R = C<sub>6</sub>H<sub>5</sub>  
 b, R = H  
 c, R = *n*-C<sub>3</sub>H<sub>7</sub>

The first pair of C-19 diastereomers studied in detail were XIa, obtained from the 7 $\alpha$ -acetyl derivative IIa by addition of phenylmagnesium bromide,<sup>23</sup> and XIIa, obtained from the 7 $\alpha$ -benzoyl derivative IV (nepenthone) addition of methyllithium.<sup>24</sup> The nmr spectra of

(23) W. Nagata, T. Terasawa, and K. Tori, *J. Am. Chem. Soc.*, **86**, (1964); D. R. Arnold, D. J. Trecker, and E. B. Whipple, *ibid.*, **87**, (1965).

(24) Compounds VI and VII were obtained through the courtesy of C. W. Bentley; the others were obtained by repeating the syntheses indicated by Bentley and co-workers as indicated: IV,<sup>4</sup> V,<sup>25</sup> VIII,<sup>2d</sup> X.<sup>2</sup>

(25) This compound, mp 210–212°, was synthesized by the Grignard reaction of phenylmagnesium bromide to IIa. The crude product (mp 107°, 86%) had traces of the other diastereomer XIb (by tlc), and was purified by partition chromatography.

(26) This compound, mp 148–150°, was synthesized by the addition of methyllithium to IV. It was initially obtained as a glass (90% yield) and

XIa and XIIa showed a number of general features consistent with those previously described (Table III), and the chemical shifts for H-5 $\beta$  in both of these C-19 diastereomers (Table I) indicated they were 7 $\alpha$  epimers; the C-7 configuration had not been affected during their synthesis. However, in XIIa the upfield shift of both olefinic protons, H-17 ( $\delta$  4.88;  $\Delta\delta$  = 0.55 ppm) and H-18 ( $\delta$  5.04;  $\Delta\delta$  = 0.91 ppm), was striking and somewhat unexpected when compared with these chemical shifts in XIa and in virtually all analogous compounds (see Table III). These upfield shifts in XIIa are understandable if the phenyl moiety (R) in this diastereomer is held in a "down under" position in close proximity to the C-17 and C-18 protons of the *endo*-etheno bridge (as illustrated in XI and XII), thereby producing a shielding effect. Examination of models indicated this was possible, and the greater upfield shift of H-18 over that of H-17 was consistent with the closer proximity of H-18 to the phenyl group. There appeared to be considerable restriction of free rotation about the C-19 to C-7 bonds in both diastereomers (XIa and XIIa), and high-temperature nmr experiments provided experimental data consistent with these observations. In perdeuteriodimethyl sulfoxide the C-19-hydroxyl resonance of XIa was observed at  $\delta$  4.9 at ambient temperature and moved upfield to  $\delta$  4.7 at 180°. In XIIa, this hydroxyl absorption was found at  $\delta$  4.6 at ambient temperature, at  $\delta$  4.4 at 140°, and at 180° it was too diffuse to locate. There were no significant changes (more than  $\delta$  0.05) from the ambient temperature spectra for any other protons.

Intramolecular hydrogen bonding<sup>25</sup> of the C-19-*t*-hydroxyl proton was evident from the infrared spectra of both diastereomers XIa and XIIa (OH, 2.92  $\mu$ ; not concentration dependent). This must involve the 6-methoxyl groups as indicated by the conformations shown in XI and XII. Hydroxyl resonances at  $\delta$  5.26 and 5.8 in the deuteriochloroform spectra of XIa and XIIa, respectively, also agreed with these hydrogen-bonded conformations.<sup>26</sup> The conformation shown for XIIa with the *t*-hydroxyl near the 6-methoxyl group and the phenyl group near the *endo*-etheno bridge thus fixed the configuration of this C-19 asymmetric center as 7 $\alpha$ -( $\alpha$ -(*R*)- $\alpha$ -hydroxy- $\alpha$ -methylbenzyl).<sup>27</sup> The isomer XIa then had to have the opposite 7 $\alpha$ -( $\alpha$ -(*S*)- $\alpha$ -hydroxy- $\alpha$ -methylbenzyl) configuration as shown. These assignments for the C-19 diastereomer configurations in XIa and XIIa, obtained solely from spectral data, are entirely consistent with conclusions suggested by chemical data, including the high degree of stereoselectivity observed during the synthesis of a variety of C-19 diastereomeric alcohols.<sup>2b</sup>

Close inspection of the nmr spectra of XIa and XIIa revealed other relationships which appeared to be consistent with the assigned conformations of these diastereomers although they are probably less definitive. Models of XIIa indicated that the edge of the phenyl moiety is directed toward H-8 $\alpha$ . Thus, a deshielding effect from the phenyl group may be responsible for the

tlc indicated a trace amount of XIa. Purification by partition chromatography then gave crystalline material which was free from the diastereomer XIa (by nmr and tlc).

(25) L. J. Bellamy, "The Infrared Spectra of Complex Molecules," Methuen and Co., Ltd., London, 1954, p 89, gives 2.8–2.9  $\mu$  for intramolecularly hydrogen-bonded hydroxyl stretching.

downfield position ( $\delta$  1.22) of this  $8\alpha$  proton in XIIa as compared with H- $8\alpha$  ( $\delta$  0.60) in XIa. There were other differences such as the C-19-methyl singlet in XIa which appeared at  $\delta$  1.42 compared with  $\delta$  1.52 in XIIa. In XIa, the H- $8\beta$  pattern had apparently shifted slightly upfield ( $\delta$  < 2.7), since the  $\delta$  2.7–3.5 region integrated for only two protons, which were assigned as H- $9\alpha$  and H- $10\beta$ . In the spectrum of XIIa and most other carbinols, this  $\delta$  2.7–3.5 region integrated for three protons, one of which was H- $8\beta$  in addition to H- $9\alpha$  and H- $10\beta$ . Another difference between the spectra of XIa and XIIa was found in the chemical shifts of the N-methyl groups. In the spectrum of XIIa, the N-methyl singlet ( $\delta$  2.36) appeared at a position consistent with the other compounds studied (see Table III). In contrast stood the upfield shift of the N-methyl singlet ( $\delta$  2.17) in the spectrum of XIa; a satisfactory explanation of these phenomena is not readily apparent.<sup>28</sup>

The second pair of C-19 diastereomers studied in detail (both nmr and infrared) were the secondary alcohols XIb<sup>29</sup> and XIIb,<sup>30</sup> obtained from the 7 $\alpha$ -acetyl derivative IIa.<sup>25</sup> These nmr spectra had general features in agreement with the values in Table I and Table III. The nmr spectrum of XIIb showed the C-19-hydroxyl proton resonance at  $\delta$  4.92, suggesting hydrogen bonding (with the 6-methoxyl) as discussed with the previous diastereomers XIa and XIIa. Infrared studies also indicated an intramolecular hydrogen bond in XIIb (2.90  $\mu$ , not concentration dependent) equivalent to the previous findings. In contrast, the C-19-hydroxyl resonance in the nmr spectrum of XIb was found at ca.  $\delta$  2.2. Parallel infrared studies with XIb showed maxima at both 2.78 and 2.86  $\mu$  (neither of which was concentration dependent) suggesting that this C-19 hydroxyl exists in two conformers, one with a weak hydrogen bond (2.86  $\mu$ ) and one with a "free" hydroxyl (2.78  $\mu$ ).<sup>30</sup> In addition to these indications of weaker hydrogen bonding, the H- $8\alpha$  lines were found at  $\delta$  1.20 in the nmr spectrum of XIb, while in its diastereomer XIIb, H- $8\alpha$  was observed at  $\delta$  0.69. In the previous pair of diastereomers XIa and XIIa (see above), the difference in chemical shifts for the H- $8\alpha$  protons could be ascribed to the deshielding edge of the "down under" phenyl group in XIIa directed toward H- $8\alpha$  and held rather firmly by steric constraints to rotation. An explanation for the opposite chemical shifts for H- $8\alpha$  in XIb and XIIb is not readily apparent. Comparative data were also obtained with the primary alcohol X in which the C-19 hydroxyl did not appear to be hydrogen bonded (infrared, 2.86  $\mu$ , not concentration dependent; nmr,  $\delta$  2.6). The location of H- $8\alpha$  ( $\delta$  0.52) in X, however, was similar to that of H- $8\alpha$  in the hydrogen-bonded secondary carbinol diastereomer XIIb. Thus, satisfactory interpretation of the range of chemical shifts (ca.  $\delta$  1.2–0.5) observed for H- $8\alpha$  in these very closely related structures was difficult (see below).

(28) The upfield shift of the N-methyl singlet and the apparent upfield shift of H- $8\beta$  in this diastereomer are unique among all of the spectra examined, and may be due to the C-19 phenyl group held in an "up" position. However, any interpretation of these factors which may be related appears to be speculative in the absence of additional examples.

(29) This compound, XIb, mp 73–75°, was obtained as a Grignard reduction by-product from the reaction of IIa with propylmagnesium iodide as described by Bentley and coworkers;<sup>25</sup> it was isolated by chromatography of the mother liquors after separation of XIc.

(30) Bentley and co-workers<sup>25</sup> have attributed the band at 2.78  $\mu$  to a conformation with the C-19 hydroxyl bonded to the C-17–C-18 double bond.

Although these detailed interesting differences between binol diastereomers XIb and XIIb preclude definitive conclusions concerning configuration at C-19. Assignments (shown in XIb and XIIb) are based on chemical data.<sup>25</sup>

The third diastereomer pair methyl tertiary carbinols XIc from the 7 $\alpha$ -acetyl (IIa) and respectively. The nmr spectrum completely in accord with all listed in Table III, and the H- $8\alpha$  in XIc;  $\delta$  4.55 in XIIc were consistent with the configuration. The C-19 hydroxyl in both diastereomers ( $\delta$  4.8) as in XIa and XIIa. Thus, diastereomers were virtually identical and provided no assignment of the absolute configuration. These were assigned by analogy, assuming of similar stereochemistry<sup>25</sup> (XIa–g, all obtained by crystallographic analysis of confirmed the configuration of XI and XII, bonded conformation of the C-19).

Compounds XIId–g,<sup>31</sup> including diastereomers whose nmr spectra patterns previously discussed shift data are included in the Tables I and III). These data were consistent with the assignments did not permit conclusions concerning diastereomeric configurations. chemical analogy.<sup>25</sup> Compounds of particular interest as it is a very derivative whose biological activity has been intensively studied;<sup>32</sup> its nmr spectrum identical with that of XIc but lacked the 3-methoxyl singlet in XIc; this indicated that no reaction had taken place during its synthesis (alkaline hydrolysis).<sup>25</sup>

#### Additional Studies of the C-8 Protons

As these nmr studies of the C-19 diastereomers progressed, the C-8 protons became increasingly important by the sometimes unexpected shifts. The proximity of the H-nitrogen atom has already been noted (of H- $8\beta$ ). Both C-8 protons are shifted by the C-17–C-18 part of the bicyclo[2.2.2]octane system; the *endo*- and *exo*-proton shifts may well apply to our compounds.

(31) This compound was synthesized by propylmagnesium iodide to IIa as described by Bentley and coworkers.<sup>25</sup>

(32) Private communication from J. Bentley, to be published.

(33) Compound XIId was obtained by hydrolysis in diethylene glycol at 200°C by co-workers.<sup>25</sup> Compounds XIe–g, in Reckitt and Sons Ltd., Laboratories at Bentley.

II <sup>e</sup>	-0.14	+0.21	-0.81	...

In none of the experiments (CF<sub>3</sub>COOH-CDCl<sub>3</sub>) did additional experiments of acid move either the H-9 $\alpha$  or N-methyl lines farther upfield (indicating complete protonation of the *t*-nitrogen). In the experiment on IIIa, the acid was added to the CDCl<sub>3</sub> solution in small increments and both the H-8 $\alpha$  and N-methyl absorptions were observed moving downfield simultaneously as the acidity increased. <sup>c</sup> In each case, after recording the protonated spectra, acid was neutralized with dilute NaOD-D<sub>2</sub>O until the spectra of the original bases were recovered (establishing the absence of composition). <sup>d</sup> In these spectra, the H-8 $\beta$  lines could not be located because of overlap with other proton lines, presumably H-5 $\alpha$  and H-16 $\beta$ . <sup>e</sup> The N-cyano derivative (not protonated) was included for comparison. <sup>f</sup> The N-methyl absorption was a broadened singlet in all cases studied.

tions in our C-7 epimers and C-19 diastereomers are primarily influenced both by the nature of and the stereochemical orientations of the C-7 substituents. This section describes further studies of these apparently unique chemical shifts directed toward a better correlation of the observed chemical shifts with structural and environmental factors responsible for them.

The N-cyano derivative IX, obtained from IIIa, and intermediate for N-substituted derivatives,<sup>3c</sup> is a compound in which the basicity of the nitrogen is diminished by the nitrile moiety. Although anisotropic effects of the nitrile group might distort some chemical shifts, spin-decoupling techniques were used to locate the H-8 $\alpha$ , H-8 $\beta$ , H-7 $\beta$  spin system in IX (as in Ia-IIIa). The lines for H-8 $\beta$  in the spectrum of IX were located centered at  $\delta$  2.67, slightly upfield ( $\Delta\delta$  = +0.21 ppm) from this pattern in IIIa, probably because of the reduced basicity of the ring nitrogen. The H-8 $\alpha$  lines at  $\delta$  0.93, the upfield "handle" for the spin decoupling, were slightly downfield ( $\Delta\delta$  = -0.14 ppm) from those in the precursor (IIIa). Both of these changes can be ascribed to the effects of the diminished proton availability on the ring nitrogen. The third line in this spin system, H-7 $\beta$ , was found at  $\delta$  2.04, shifted slightly upfield ( $\Delta\delta$  = +0.06 ppm) from its position in the spectrum of IIIa. Interestingly, the H-16 $\alpha$  lines moved downfield ( $\Delta\delta$  = -0.7 ppm) to about  $\delta$  3.1 and overlapped with the lines from H-10 $\beta$  (H-16) which did not change from their position in the spectrum of IIIa. The H-9 $\alpha$  absorption ( $\delta$  3.93) moved downfield ( $\Delta\delta$  = -0.81 ppm from IIIa) as expected. Other proton absorptions maintained their positions (0.05 ppm) compared with IIIa.

Since the nmr spectrum of IX (ring nitrogen with diminished electron density) indicated that the H-8 $\alpha$  and H-8 $\beta$  lines had moved toward each other, further studies were undertaken with a number of protonated derivatives. These were carried out with an isolated hydrochloride or by the addition of trifluoroacetic acid to deuteriochloroform solutions of the free bases. The results are summarized in Table IV ( $\Delta\delta$  shifts for H-8 $\alpha$ , H-8 $\beta$ , H-9 $\alpha$ , N-Me). In the spectrum of the hydrochloride of IIa (the 7 $\alpha$ -acetyl epimer), H-8 $\alpha$  had moved

downfield about 0.3 ppm, but, unfortunately, the H-8 $\beta$  lines could not be observed because of overlap with other lines (H-16 $\alpha$  and H-16 $\beta$  would be expected to shift downfield upon protonation of the ring nitrogen). H-1 and H-2 moved slightly downfield ( $\Delta\delta$  = -0.15 and -0.14 ppm, respectively), as did H-17 ( $\Delta\delta$  = -0.24 ppm). Both H-9 $\alpha$  and the N-methyl resonance lines showed the expected downfield shifts (Table IV) and the N-methyl absorption was a broadened singlet in all cases. No other proton absorptions which could be identified by observation had moved, compared with the spectrum of the base.

The nmr spectrum of the primary alcohol X as the conjugate with trifluoroacetic acid showed similar shifts. The H-8 $\alpha$  lines moved downfield by ca. 0.3 ppm (to  $\delta$  0.83) and the H-8 $\beta$  lines were tentatively identified at  $\delta$  2.5, an upfield shift of ca. +0.4 ppm compared with the base. In this case, then, the difference between the chemical shifts of the geminal pair, H-8 $\alpha$  and H-8 $\beta$ , was reduced from ca. 2.4 to ca. 1.7 ppm upon protonation of the ring nitrogen.

Spectra of protonated conjugates of the following compounds were also studied: the dimethyl tertiary carbinol IIIa and the diastereomeric secondary carbinols XIb and XIIb. The results of these experiments were similar to those just described (with IIa and X). All of these protonation experiments (Table IV) indicated a downfield shift for H-8 $\alpha$  which varied somewhat with different C-7 substituents. There is a possible progression for the tertiary carbinol IIIa, the secondary carbinol XIIb, and the primary carbinol X. In their nmr spectra, the H-8 $\alpha$  lines were found at  $\delta$  0.79, 0.69, and 0.52, respectively. In the presence of CF<sub>3</sub>COOH and in the same order, the H-8 $\alpha$  lines were observed at  $\delta$  1.0, ca. 1.0, and 0.83, respectively. In the two cases where H-8 $\beta$  could be located, the lines for these protons were found to have shifted upfield. The constancy of the downfield shifts for H-9 $\alpha$  and the N-methyl protons was also apparent (Table IV). These experiments clearly indicated that at least part of the large difference between the H-8 $\alpha$  and H-8 $\beta$  chemical shifts is due to shielding by the ring nitrogen, rigidly held by the fused ring system. This effect is analogous to that found by Winstein and co-workers<sup>35</sup> for the hydroxyl group in half-cage hydrocarbons, but smaller in magnitude.

High- and low-temperature nmr experiments were performed on the tertiary carbinol IIIa, the secondary carbinol XIIb, and the primary carbinol X, and a low-temperature experiment only on XIb. The purpose was to investigate any observable effects on the H-8 $\alpha$  chemical shifts by possibly inducing more rotation about the C-19 to C-7 bond, or the effects of any additional conformers. The high-temperature experiments were run using *o*-dichlorobenzene as the solvent. The probe temperature was raised to  $180 \pm 2^\circ$  without any diagnostic changes occurring from the observed ambient temperature spectra (essentially the same as deuteriochloroform spectra). In each case, of course, the hydroxyl absorption moved upfield and usually became too diffuse to locate. In the low-temperature experiments, deuteriochloroform was used as the solvent, and the probe temperature was lowered to  $-50$

# The Crystal and Molecular Structure of Triclinic Tetraphenylporphyrin

Stuart J. Silvers and A. Tulinsky<sup>1</sup>

*Contribution from the Sterling Chemistry Laboratory, Yale University, New Haven, Connecticut. Received February 13, 1967*

**Abstract:** The crystal and molecular structure of triclinic tetraphenylporphyrin (TPP) has been solved using X-ray crystallographic techniques. The molecule is centrosymmetrical with two independent pyrrole and phenyl groups. Although the individual pyrrole and phenyl groups are planar within the error of their determination ( $<0.005$  Å), the porphyrin ring is nonplanar. One pair of centrosymmetrical pyrroles is essentially coplanar with the nuclear least-squares (NLS) plane of the porphyrin ring; the other pair, carrying the central hydrogen atoms, is inclined  $\pm 6.6^\circ$  to this plane. The tilt of the latter is such that the distance between the central hydrogens is increased by 0.2 Å, to 2.36 Å. Both phenyl groups of TPP are rotated out of the NLS plane by about  $60^\circ$ ; one phenyl is additionally inclined to this plane by  $\pm 9.1^\circ$ . Although the porphyrin ring is nonplanar, the atoms of the inner 16-membered ring are individually planar, and the bond distances of this ring resemble those of a heterocyclic aromatic system. The 1,2 and 3,4 bond lengths of the independent pyrroles correspond closely to isolated double bonds and to this extent appear isolated from the inner ring; the phenyl groups also appear to be electronically isolated from the ring through shortened single bonds. The structure described herein corresponds closely with the hybrid of the two classical resonance forms of the porphyrin molecule. Finally, the fine points of the structure are discussed in terms of the molecular packing in the crystal.

Tetraphenylporphyrin ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ) ( $C_{44}H_{30}N_4$ , see Figure 2), hereinafter referred to as TPP, is a synthetic nonmetalloporphyrin derivative. TPP is related to naturally occurring porphyrins by having the same macrocyclic skeletal structure, which consists of four pyrrole groups alternately linked through methine carbon bridges.

The metalloporphyrin ring is found in a variety of important biological systems where it is either the active component of the system or in some way intimately connected with the activity of the system. Many of these biological porphyrin systems differ markedly in their behavior and it appears that this is due in large part to: (a) the effects of a central metal ion on the bonding system of the porphyrin ring, (b) the ease with which the porphyrin ring can assume various nonplanar conformations, (c) the chemistry and the stereochemistry of side chains of the porphyrin ring, and (d) the general molecular environment of the porphyrin in the biological system.

Porphyrins also possess an intrinsic interest in that they are examples of an extremely stable heteromacrocyclic  $\pi$ -bonding system with the ability to complex readily with many different metal ions. Although there are other ligands that behave similarly, the porphyrins are unusual in that they, as the ligand, act as the host to the metal ion. In the case of free-base porphyrins, additional interest centers about the exact nature of the central acidic hydrogen atoms. If the porphyrin skeleton were planar or nearly so, the two central hydrogens bound to opposite pyrrole groups would approach one another within about 2.0 Å. This would need a close van der Waals contact and at the onset of this work, it seemed unlikely. Therefore, in the beginning, the nature of the central hydrogen atoms and their environment were of most concern to this structural determination. However, it has resulted since that other structural characteristics of the molecule of at least equal interest.<sup>2,3</sup>

## Experimental Section

Single crystals of TPP were grown by slowly evaporating solutions of TPP in benzene, chloroform, and dioxane.<sup>4</sup> All the crystals were elongated purple prisms, but those grown from benzene and chloroform were soft and did not diffract X-rays well. The crystals from dioxane, grown under a nitrogen atmosphere, were hard, slightly translucent, and good X-ray scatterers. One of these crystals, with approximate dimensions of  $0.75 \times 0.20 \times 0.05$  mm and with well-developed end faces, was used for X-ray examination because of its size and apparent crystal quality.

All the X-ray work was carried out with Cu  $K\alpha$  radiation and a General Electric XRD-5 equipped with a single-crystal orienter and a scintillation counter assembly. A survey of the diffraction pattern indicated that the crystal system was triclinic. By convention, the unit cell was chosen to be primitive and reduced with the three axes forming a right-handed coordinate system. The unit cell so chosen has the dimensions:  $a = 6.44 \pm 0.01$ ,  $b = 10.42 \pm 0.01$ ,  $c = 12.41 \pm 0.01$  Å,  $\alpha = 96.06 \pm 0.05^\circ$ ,  $\beta = 99.14 \pm 0.05^\circ$ ,  $\gamma = 101.12 \pm 0.05^\circ$ ,  $V = 801.9 \pm 1.2$  Å<sup>3</sup>. The crystal density calculated on the basis of these dimensions and one molecule of TPP per unit cell is 1.273 g/cm<sup>3</sup>. The density of several single crystals was measured to be  $1.27 \pm 0.01$  g/cm<sup>3</sup> by suspending the crystals in a solution of silver nitrate and water. Thus, the number of molecules per unit cell was taken to be one.

In the triclinic case the required intensity data are confined within half of the limiting sphere. Since the single-crystal orienter used in this work was a quarter-circle model, once the crystal was mounted the segment of the sphere to be collected was fixed. Mosaic spreads of several reflections were therefore measured only to ensure that the crystal quality was sufficient for intensity data collection purposes. The spreads proved to be symmetrical and ranged from 0.3 to 0.6° in width, from background to background.

The intensities of the reflections were measured by the stationary crystal-stationary counter technique. In order to avoid  $K\alpha_1$  and  $K\alpha_2$  splitting effects, the data collection was confined to reflections with scattering angles ( $2\theta$ ) less than  $110^\circ$ , which corresponds to 0.94-Å resolution. Of the 2007 independent reflections possible to this limit, the intensities of 1726 (86%) were large enough to be observed. During the intensity measurements the crystal was exposed to X-rays for about 33 hr, but its reflecting power was

not thereby altered; the intensities of four reflections which were monitored throughout the measurement period remained constant.

The intensities were corrected for absorption with a correction obtained by averaging intensity *vs.*  $\phi$  curves (azimuthal orientation) of two reflections with  $\chi$  values of  $90^\circ$ ; the average curve had a maximum:minimum ratio of 1.10. The intensities so corrected were converted to structure amplitudes, and the latter were then scaled with the results of Wilson's method to approximate an absolute scale.

### Structure Determination

**The Center of Symmetry.** The observed reflections were divided according to scattering angle into five groups. These were: (1)  $2\theta < 30.00$ , (2)  $30.00 \leq 2\theta < 56.16$ , (3)  $56.16 \leq 2\theta < 75.00$ , (4)  $75.00 \leq 2\theta < 92.99$ , and (5)  $92.99 \leq 2\theta \leq 110.00^\circ$ . The first group, containing 50 reflections, was ignored in further considerations for theoretical reasons.<sup>5</sup> For each of the other four, the percentage,  $N(z)$ , of reflections with  $|F|^2$  less than or equal to a fraction,  $z$ , of the group average was plotted as a function of  $z$ . The unobserved reflections were included with zero structure amplitudes. In Figure 1, the average of these plots is indicated by open circles and the two theoretical distributions for P1 and  $\bar{P}1$  are shown by solid curves. Clearly, the observed  $|F|^2$  distribution is centrosymmetric and the space group of the crystal is therefore  $\bar{P}1$ .

**The Patterson Function and the Orientation of TPP.** Since there is only one TPP molecule per unit cell and the space group is  $\bar{P}1$ , the molecule itself must be centrosymmetric. By taking the molecular center of symmetry as the unit cell origin, the translational parameters of TPP are fixed. Since the gross structure of the molecule was known, the determination of a trial structure reduced simply to the determination of an approximate angular orientation for the molecule.

In order to determine the angular orientation of the TPP molecule, a three-dimensional Patterson function was computed using the squares of the observed amplitudes as coefficients. The significant positive regions of this function were confined to the region of the plane which is parallel to the  $(1\bar{2}1)$  planes and passes through the origin. If the vectors between atoms lie close to a plane, the atoms themselves also must lie close to that plane. Therefore, the  $(1\bar{2}1)$  plane was concluded

to be the approximate mean plane of the molecule. In support of this conclusion, the structure amplitudes of the  $(1\bar{2}1)$ ,  $(1\bar{3}1)$ , and  $(1\bar{2}0)$  reflections were, in that order, the largest reflections of all those observed and significantly so.

At this stage, the molecule was assumed to be strictly planar except for undertermined rotations of the four phenyl groups about the bonds joining them to the bridge carbon atoms between the pyrroles. The mean plane of the molecule, in accordance with the Patterson function, was taken to pass through the origin and lie parallel to the  $(1\bar{2}1)$  planes. Thus, there remained to be determined only the orientation of the model molecule within this plane. As a further simplification, this planar model of TPP was assigned a fourfold rotation axis so as to fix its orientation within  $90^\circ$ .

The model was then systematically rotated about its fourfold axis 12 times ( $7.5^\circ$  each time). In this way, the "correct" orientation would approach within  $3.75^\circ$  of one of these 12 positions (since a  $90^\circ$  rotation superimposes the model upon itself). For each orientation the coordinates of the model molecule (excluding the four atoms of each phenyl group which were expected for steric reasons to lie rotated out of the plane) were determined and a set of structure factors was computed. An over-all isotropic thermal parameter of  $2.0 \text{ \AA}^2$ , estimated from Wilson's method, was used in each calculation. The  $R$  value for each set of structure factors was then examined as a function of the orientation of the model. The  $R$  values fluctuated about the value of  $0.73 \pm 0.03$  but one was considerably smaller than all the others (0.68). The point Patterson function of the model in the orientation corresponding to this minimum  $R$  was then compared with the observed Patterson in the  $(1\bar{2}1)$  plane. Since the principal features of the two were in good agreement the orientation of the TPP molecule was taken to correspond with the minimum  $R$  value.

The phases of this set of structure factors were assigned to the observed amplitudes and an electron density ( $\rho_1$ ) was computed. The carbon and nitrogen atoms of the porphyrin nucleus all appeared in  $\rho_1$  at peak heights of approximately  $6 \text{ e\AA}^{-3}$  or more. However, the positions of these peaks were in some cases noticeably different from those of the model structure. This was expected, since the deduced orientation of the model was not exact and its planarity and fourfold symmetry were approximations.

The eight next-to-the-largest peaks in  $\rho_1$  (average peak height of  $3.7 \text{ e\AA}^{-3}$ ) besides those of the 16 model atoms were recognized to be the phenyl carbon atoms not included in the model. The terminal atom of one phenyl group in the model appeared in  $\rho_1$  as an atom adjacent to the true terminal position. This phenyl group, as observed in  $\rho_1$ , was thus bent out of the plane of the model as well as rotated about the bond from its proximal atom to the porphyrin ring. The other phenyl group was not bent out of the plane but only rotated and its terminal atom corresponded to that of the model. Thus, although the phases employed to obtain  $\rho_1$  were determined by a model which was a considerable oversimplification of the true structure, nevertheless, they were able to reveal a structure that was neither planar nor fourfold symmetrical, which corresponded in most of its essentials to that of the final structure.

\* Anisotropic temperature factor =  $\exp[-(\beta_{11}h^2 + \beta_{22}k^2 + \beta_{33}l^2 + 2\beta_{12}hk + 2\beta_{13}hl + 2\beta_{23}kl)]$ .

## Refinement of the Structure

**The Fourier Refinement.** New atomic coordinates were obtained from  $\rho_1$  for all the carbon (22) and nitrogen (2) atoms; they were used to compute a new set of structure factors and the new phases were used to compute  $\rho_2$ . The phenyl groups in  $\rho_2$  were all of the order of 5–6 eÅ<sup>-3</sup> at peak height and their positions indicated considerable shifts from their  $\rho_1$  coordinates. Coordinates from  $\rho_2$  were used to begin a series of four structure-factor and related electron- and difference-density computations. Individual isotropic temperature factors were introduced after one cycle and the *R* factor went 0.46, 0.33, 0.19, and 0.16 for the four cycles of refinement. The last difference density showed clearly positive and negative regions in the vicinity of atomic positions, indicating anisotropic thermal motion. At this state it was decided to introduce anisotropic thermal parameters and to continue the refinement by the method of least squares.

**The Least-Squares Refinement.** A weighting scheme similar to that of Hughes was chosen for the least-squares refinement. For  $|F_o| \leq 6.0$ , the assigned weight was  $1/(0.6)^2$ , and for  $|F_o| > 6.0$ , it was  $1/(0.1|F_o|)^2$ . The initial parameters for least-squares refinement were those of the last Fourier cycle. These included isotropic temperature factors which, before conversion to anisotropic, were varied with scale factor for two cycles of least-squares refinement. The shifts from the second cycle were small and isotropic refinement was terminated at *R* = 0.122.

Refinement including anisotropic thermal parameters proceeded by varying the thermal parameters of only six atoms per cycle. The four groups of six atoms chosen were the two phenyl and the two pyrrole plus methene bridge atom groups. The groups were chosen to be physically distinct, since only the temperature parameters of atoms adjacent to one another are likely to have interdependent shifts. Each group of thermal

parameters (6 per atom, 36 total) was varied for one cycle. At the end of these four cycles, the *R* factor was 0.091.

A difference density was then computed based on the last structure-factor computation. The 15 largest peaks in this density, varying from 0.3 to 0.6 eÅ<sup>-3</sup>, were located in the vicinity expected for the 15 hydrogen atoms of the asymmetric unit. They included the peak of the central hydrogen atom whose location was of particular interest. The hydrogen atoms, each with coordinates taken from the difference density and anisotropic thermal parameters identical with the atoms to which they were bonded, were included in the structure factors computed for the next least-squares cycle. This cycle varied the positions of all carbon and nitrogen atoms and the position and thermal parameters of the central hydrogen atom. The adjusted thermal parameters of the central hydrogen were not positive definite; consequently, the changes were ignored. A new set of structure factors was computed and these were used to compute a final difference density. The regions of all the atomic positions in this density were close to zero and, except for hydrogen atoms, no significant parameter shifts were indicated. The largest positive regions were of the order of 0.2 eÅ<sup>-3</sup>. A final structure factor computation included all 39 atoms. The hydrogen atom coordinates for this computation incorporated shifts from the final difference density; all other atomic parameters were those of the last least-squares cycle. The final value of *R* was 0.056.

## Results

The final coordinates and anisotropic thermal parameters of the carbon and nitrogen atoms are listed in Table I, the atoms therein labeled according to Figure 2. Hydrogen atom coordinates are given in Table II; their thermal parameters are the same as the atoms to which they bond. In Table III are listed the three

Figure 2. Deviations (in Å) of the atoms of TPP from the nuclear least-squares plane (NLS). The labeling system of the atoms is also shown.

principal axes of the thermal ellipsoid of each atom, the direction cosines of each principal axis with respect to the direct cell axes, and the mean-square atomic displacement along each principal axis.

A plane was fitted to the 24 carbon and nitrogen atoms of the porphyrin nucleus by the method of least squares.<sup>6</sup> The determined plane, which necessarily passes through the center of symmetry of the molecule, has the equation of  $(3.799)x - (9.112)y + (3.042)z = 0$ . In Figure 2, the perpendicular distances of the atoms from this plane are given. Least-squares planes were determined similarly for the individual phenyl and pyrrole groups of TPP. For comparison, the distances of the respective atoms from these planes are given in Table IV.

$\sigma$	0.004	$\sigma$	0.003

Standard deviations of the carbon and nitrogen atom coordinates and the thermal parameters were obtained from the least-squares refinement. Their range is indicated at the end of Table I. The atomic parameters are determined most accurately in the porphyrin nucleus, less accurately in phenyl  $\alpha$ , and least accurately in phenyl  $\beta$ . The standard deviation of the final electron and difference densities is estimated at  $0.15\text{--}0.20\text{ eA}^{-3}$ . The standard deviations of the lengths and angles of the carbon-carbon and carbon-nitrogen bonds are approximately  $0.005\text{--}0.01\text{ Å}$  and  $0.5\text{--}0.8^\circ$ , respectively; those of the carbon-hydrogen and nitrogen-hydrogen bond distances are of the order of  $0.05$

Figure 4. Hydrogen atom regions for TPP viewed perpendicular to the NLS plane. Contours at  $0.1\text{-eA}^{-3}$  intervals, starting at  $0.2\text{ eA}^{-3}$ , ----.

A. Again, the accuracy is better for the bonds and angles of the porphyrin nucleus than for those of the phenyl groups.

#### Discussion of the Results

From Figure 2, it can be seen that the TPP molecule in the triclinic crystal form is significantly nonplanar in several respects: the phenyl and pyrrole rings are separately planar within the error of their determinations (see Table IV) but they are rotated and inclined with respect to the nuclear least-squares (NLS) plane of the molecule.

The N-1 pyrrole groups are tilted out of the NLS plane about an axis lying in the plane and passing through the C-2-C-6 and C-1-C-5 bonds. The perpendicular to the N-1 pyrrole plane makes a  $6.6^\circ$  angle with that of the NLS plane. The N-2 pyrrole groups are only tilted  $1.4^\circ$  with respect to the NLS plane about an axis through C-7 and the C-4-C-8 bond. The former and larger tilt causes the central hydrogen atom of one N-1 pyrrole group to lie  $0.18\text{ Å}$  above the NLS plane and that of the centrosymmetrically related group to lie the same distance below. Consequently, the distance between the two central hydrogen atoms ( $2.36\text{ Å}$ ) is about  $0.2\text{ Å}$  greater than it would be for a planar conformation.

As the relationships of the two types of pyrrole group to the NLS plane differ, so do those of the two types of phenyl group. The 1-4 axis of phenyl  $\alpha$  is tilted much more with respect to the NLS plane than is the same axis of phenyl  $\beta$ , and in a different manner. The phenyl  $\alpha$  1-4 axis makes a  $9.1^\circ$  angle with its projection onto the NLS plane and intercepts the plane near C- $\alpha$ ; the corresponding angle for the phenyl  $\beta$  axis is only  $0.8^\circ$ . If the phenyl groups were coplanar with the NLS plane, then to transform them to their true positions, they must be first tilted along their 1-4 axis so that atoms 1 and 4 are in their correct positions, and then the phenyl groups must be rotated about these axes. The required angles of tilt are given above; the rotation angles are  $61.0^\circ$  for phenyl  $\alpha$  and  $63.1^\circ$  for phenyl  $\beta$ .

Figure 5. Distances (in Å) and bond angles (in degrees) for TPP. Bonds to hydrogen atoms are broken.

The phenyl groups are thus rotated more than  $60^\circ$  out of the NLS plane and, furthermore, the  $\alpha$  groups are tilted so the  $\phi_{\alpha-4}$  lies 0.68 Å from the plane. The phenyl rotation is as expected, since otherwise the phenyl hydrogen atoms proximal to the porphyrin ring would interfere with the pyrrole hydrogen atoms. The tilt, however, is unexpected. Conceivably, it could result from bond angle requirements of the central  $\pi$ -bonding system (preserving individual planar atoms, as is observed). However, it is more likely due to the manner in which the molecules pack. The closest intermolecular contact (3.40 Å, see Figure 6) occurs between N-1 of one molecule and  $\phi_{\alpha-2}$  of the neighboring molecule along the  $\bar{a}$  direction.

Also of note is the packing mode of the pyrrole groups of molecules adjacent along the  $\bar{a}$  direction. If the molecules are viewed along the perpendicular to the NLS plane, it is seen that an N-1 and an N-2 pyrrole group of one molecule lie, respectively, perpendicularly above an N-2 and N-1 group of the molecule below. The pyrrole pair in the upper molecule is related by a center of symmetry and an  $\bar{a}$  translation to the lower pair. The closest intermolecular contact between these pyrrole groups is 3.63 Å, from C-3 in one molecule to N-1 of the other. This contact and the way in which

phenyl groups of neighboring molecules are related are shown in Figure 6.

Temperature-factor anisotropy (see Table III) is least for atoms of the porphyrin ring; it increases for the phenyl  $\alpha$  atoms and is largest for the phenyl  $\beta$  atoms. The mean-square atomic displacements vary from atom to atom in the same manner as do the standard deviations of the atomic parameters. The mean-square displacement of a particular atom in the radial direction (toward or away from the molecular center) is usually less than in its tangential directions. The above properties of the thermal motion may probably be partly attributed to quasi-rigid angular oscillations about the molecular center. The larger mean-square displacements of phenyl  $\beta$  relative to phenyl  $\alpha$  are probably a consequence of the closer packing of phenyl  $\alpha$ .

From Figure 5, it appears that the atoms of the *interior ring* of the porphyrin skeleton form a heterocyclic aromatic system (C-5, N-1, C-6, C- $\alpha$ , C-7, N-2, C-8, C- $\beta$ ). The carbon-carbon bond distances of this system average  $1.400 \pm 0.002$  Å and the carbon-nitrogen distances average  $1.370 \pm 0.007$  Å. Furthermore, although the atoms of this system do not lie in a plane, the bonding about C-5, C-6, C- $\alpha$ , C-7, C-8, C- $\beta$  is in

6. Packing of TPP molecules of neighboring unit cells viewed in the  $-a^*$  direction. In relation to the molecule shown completely, the molecule on the left is translated along  $-a$ , the molecule on the right is translated along  $-c$ , and the molecule in the foreground is translated along  $b$  and  $a$ . Close intermolecular contacts are given (in Å).

are planar (sum of the bond angles equals  $360^\circ$ ). The C-1-C-2 and C-3-C-4 bonds of the pyrroles correspond closely in length to double bonds and to this these atoms appear to be isolated from the inner ring system with the bonds joining these four to the interior ring being shorter than normal bonds. Finally, the phenyl groups appear to be electronically isolated from the inner ring system; the phenyls are bound to the bridge positions through essentially shortened single bonds.

#### Concluding Remarks

In closing, it should be interesting to note that the pyrrole structure herein described corresponds closely to the structure expected of a hybrid of the two prevalent classical resonance forms of the porphyrin molecule. These two forms are shown in Figure 7a and b; Figure 7c is an attempt at representing the expected nature of the hybrid. Also given in Figure 7c are the carbon-carbon and carbon-nitrogen distances of the independent pyrrole groups (observed distances), the carbon-carbon distance involving the methene bridges (an observed average with a standard deviation of  $\pm 0.002$  Å) and the differences in the average distances of the independent pyrroles. Clearly, in each case, corresponding distances differ in the manner expected of the hybrid. The C-1-C-2 and the C-3-C-4 bond lengths of the pyrroles differ only by about the expected error but the differences average about three times the standard deviation.

Since a corresponding trend can also be detected considering the bond angles, the behavior is probably significant.

Figure 7. (a and b) Two dominant resonance structures of TPP. (c) Expected nature of the hybrid; the mean observed distances of independent pyrroles and differences ( $\Delta$ ) between corresponding bonds are also shown.

Biosynthesis of Cholesterol by Seedlings of *Digitalis purpurea*

Gert M. Jacobsohn and Michael J. Frey

Contribution from the Department of Biological Chemistry, Hahnemann Medical College, Philadelphia, Pennsylvania 19102. Received March 13, 1967

**Abstract:** Three- and four-week old seedlings of *Digitalis purpurea* were incubated with mevalonic acid-2-<sup>14</sup>C and found to incorporate 4.8 and 3.6% of the label into a mixture of sterols. Of the radioactivity of the sterol fraction 24–31% was found associated with cholesterol. Cholesterol comprises about 3% of the weight of all sterols. The high incorporation of radioactivity into cholesterol and its small weight compared to other sterols support the hypothesis that cholesterol is an intermediate in plant sterol biosynthesis. The sterols were found as water-soluble conjugates.

For many years cholesterol was thought to be a sterol peculiar to animals. This view could no longer be maintained when Tsuda, *et al.*,<sup>1</sup> found cholesterol in red algae; Johnson, *et al.*,<sup>2</sup> found the sterol in *Solanum tuberosum* and *Dioscorea spiculiflora*; Devys and Barbier<sup>3</sup> found it in the pollen of *Hypochoris radicata*; and Linde, *et al.*,<sup>4</sup> found it as constituent of "γ"-sitosterol from *Digitalis canariensis*. Recently, Caspi, *et al.*,<sup>5</sup> have shown that cholesterol can be degraded to pregnenolone by whole *D. purpurea* plants, and Tschesche and Lilienweiss<sup>6</sup> have demonstrated that the steroid in pregnenolone-β-D-glucopyranoside can be converted to digitoxigenin by excised leaves of *D. lanata*. These reports have led to speculation that cholesterol represents an intermediate in the biosynthesis of plant steroids. In the present paper we describe the synthesis of radiocholesterol from mevalonic acid-2-<sup>14</sup>C by seedlings of *D. purpurea*.

## Experimental Section

**Materials.** Seeds of *D. purpurea* were acquired from Burnett-Seedsman, New York, N. Y. dl-Mevalonic acid-2-<sup>14</sup>C, as the dibenzylethylenediamine salt, was purchased from New England Nuclear Corp. All chemicals were reagent grade. Methylene chloride, alcohols, benzene, and water were distilled.

**Growth and Incubation of Seedlings.** Two experiments with separate batches of seeds were performed. Experiment 1 was run 8 months prior to the other and will be described in detail. Experiment 2 differed from the first in age and amount of seedlings and quantity of administered mevalonic acid-2-<sup>14</sup>C, as indicated below.

Seeds of *D. purpurea* were grown on nutrient agar plates for 21 days at room temperature and in the dark. Seeds were briefly soaked in 95% ethanol, transferred to a 1% sodium hypochlorite solution, washed with water, and blotted on several layers of filter paper under aseptic techniques. Approximately 2400 seeds were spread over the surface of an agar plate in a glass dish, 10 cm in diameter and 8 cm high. The agar was prepared by adding 1% of Difco "Noble" agar to White's standard medium,<sup>7</sup> without the color indicator. Of this medium, 150 ml was placed into each glass dish which was then autoclaved for 30 min. The dishes, after setting of the gel and seeding, were covered and placed in a dark cabinet without further attendance for 21 days at room temperature. Of each batch of 12 dishes, one or two were usually found contaminated

with microorganisms. These were discarded as soon as noticed. If no contamination occurred during the first week after seeding, none would occur at a later time.

The seedlings were pulled from the agar after softening the latter by heating to 35°. To each of three 250-ml erlenmeyer flasks provided with silicone rubber stoppers were added 150 ml of inorganic salt solution prepared according to White,<sup>7</sup> 13.8 g of seedlings, and 1 ml of water containing 0.196 mg of mevalonic acid-2-<sup>14</sup>C as the dibenzylethylenediamine salt (specific activity 8.5 μcuries/mg). The flasks were shaken slowly for 5 days and were opened daily for 1 hr. At the end of the time period the salt solution was decanted and the seedlings were washed three times with 100 ml of water each time and blotted on filter paper.

**Isolation of Cholesterol.** All seedlings were combined, 150 ml of water was added, and the mixture was homogenized first in a Waring blender at high speed for 30 sec and then in a Potter-Elvehjem tissue grinder.

To remove fatty substances, the product was shaken thoroughly for 1 hr with 200 ml of petroleum ether (bp 60–90°) and separated. This extraction was repeated three more times. The aqueous phase was acidified to pH 4 with hydrochloric acid, and 40 g of sodium chloride was added and dissolved with stirring. The mixture was extracted four times with an equal volume of 1-butanol each time. The pooled alcoholic extracts were taken to dryness by water-pump suction at 60–70°. The dry residue was refluxed for 2 hr with 30 ml of 4 N hydrochloric acid made up by diluting one volume of concentrated hydrochloric acid with one volume of water and one volume of methanol.<sup>8</sup> After cooling to room temperature, the hydrolysate was extracted three times with 30 ml of benzene each time. The pooled benzene extracts were washed once with 10 ml of 1 N sodium hydroxide and five times with 10 ml of water and evaporated to dryness under vacuum. The residue was chromatographed on four thin layer plates of 0.50-mm-thick silica gel in the system 5% petroleum ether in methylene chloride so that the solvent front ran up a distance of 15 cm from the origin. Material corresponding to sterols by comparison with standards moved with an *R<sub>f</sub>* value between 0.13 and 0.23. Unidentified radioactivity remained at the origin and, except for the sterol spot, no significant counts were present elsewhere on the plate. The silica gel in the region between 2 and 3.5 cm was scraped off, and substances were eluted exhaustively with methanol and ethyl ether and dried.

The residue contains sterols and unidentified substances. It was subjected to a second thin layer separation on three similar plates in the system 8.5% ethanol in methylene chloride. All of the radioactivity was localized in an area between *R<sub>f</sub>* values of 0.60 and 0.73, corresponding to authentic sterols. The rest of the plate contained only background counts. The silica with the radioactive spot was scraped off and exhaustively extracted, as before. A product weighing 3.5 mg and having a total radioactivity of 23,350 cpm was obtained. One-thousandth of this material was subjected to gas chromatography.

Gas chromatography was performed on a Barber-Colman Model 10 instrument, equipped with a 150-cm U-shaped column 4 mm in diameter. The supporting medium consisted of Gas Chrom Q, 100–120 mesh, coated with 0.8% of SE-52. The column was bled at 255° for 114 hr and used for analysis at 219°. The sample injection port temperature was 270°, and the detector temperature

267°. A  $\beta$ -ionization chamber with <sup>90</sup>Sr was the detecting e. A flow rate of 52–60 cc/min of argon was maintained. Retention times were 15, 18.5, 20.5, and 24 min, respectively, cholesterol, campesterol, stigmasterol, and  $\beta$ -sitosterol. The active acetates showed peaks at 20.5, 27.5, 30, and 35 min.

One milligram of authentic stigmasterol was added to the sterol e obtained from the final thin layer chromatography plates. stigmasterol was recrystallized seven times from methanol-. The mother liquor of each stigmasterol crystallize, except st, showed a small cholesterol peak on the gas chromatogram. the residue of the seventh supernatant the cholesterol peak disappeared and the specific activity was reduced to less than half. The specific activity of crystals decreased with each successive crop, but the rate of decrease slowed down. It is likely that s were associated with stigmasterol. All supernatants were d, taken to dryness, and acetylated. One-fiftieth was subjected n layer chromatography according to the procedure of Waters ohnson,<sup>9</sup> and it was found that the major amount of radioi- ty was associated with the cholesterol acetate area. Gas natography of the acetates indicated peaks which coincided peaks for standard cholesterol, campesterol, stigmasterol, and sterol acetates. Thereupon 10 mg of cholesterol acetate was l to the combined residue, which weighed 1.3 mg, and one- er of the material was recrystallized five times.

The rest of the cholesterol acetate mixture was divided into two ons. Portion 1 was hydrolyzed with 6% potassium hyde in ethanol for 0.5 hr in a boiling water bath. Water was l and the hydrolysate was extracted with ether. After evap- on of ether a quantity of standard cholesterol approximately to the weight of the residue was added and recrystallized times. Portion 2, remaining from the above, was also lyzed and then benzoated in the usual manner. Standard sterol benzoate was added and recrystallized eight times.

Incubations in expt 2 were 29 days old and weighed 66.3 g. were incubated with a total of 0.30 mg of mevalonic acid-2-<sup>14</sup>C, e dibenzylethylenediamine salt (specific activity 7.0  $\mu$ curies/

The seedlings were homogenized, as described, sonicated for i, homogenized again, and resonicated. This procedure was l necessary in order to break up all of the cells, as determined w-power microscopy. To the residue, after thin layer chro- graphy in both systems described, was added 10 mg of chole-

The latter was crystallized five times.

Scintillation counting was done on a Nuclear Chicago Series 720 ometer at room temperature with enough radioactive material net count at least double the background rate and for most les appreciably more. The scintillation fluid consisted of 10 a solution of toluene, containing 5 g of 2,5-diphenyloxazole 300 mg of 1,4-bis(2-(5-phenyloxazolyl))benzene per liter. counting time varied between 20 and 100 min. The efficiency 78%. The mevalonic acid-2-<sup>14</sup>C was dissolved in 0.5 ml of anol before the scintillation fluid was added.

## Results

Table I shows the specific activity of the sterol crystals and the mother liquors from each crystallization of expt 1, obtained after incubation with mevalonic acid-2-<sup>14</sup>C. In three instances residues from the final supernatants were too small to be transferred to a micro- nce. The radioactivity of stigmasterol decreased

<sup>a</sup> Counts per minute per milligram.

throughout the crystallization steps, but the rate of decrease appears to approach asymptotically a level above 1200 cpm/mg. The pooled petroleum ether extracts of the defatting stage contained a total of 38,500 cpm. Analysis by gas chromatography showed a number of peaks appearing during the first 17 min. No peaks corresponding to the four sterols assayed here could be detected in this fraction. The aqueous phase contained 453,000 cpm. Gas chromatography of the sterol mixture in the aqueous phase after hydrolysis and separation in both thin layer systems indicated the presence of 0.075 mg of cholesterol, 0.43 mg of campesterol, 1.44 mg of stigmasterol, and 1.64 mg of  $\beta$ -sitosterol, by comparison with standards.

The petroleum ether extracts from expt 2 contained 1360 cpm and the aqueous phase 1,460,000 cpm. Quantitation of sterols by planimetry of gas chromatograph peaks gave the following values: 0.175 mg of cholesterol, 0.80 mg of campesterol, 1.69 mg of stigmasterol, and 2.00 mg of  $\beta$ -sitosterol. The specific activities of crystallized cholesterol and the residues from the mother liquors are indicated in Table II.

## Discussion

Incubation with mevalonic acid-2-<sup>14</sup>C permits the isolation of cholesterol acetate, cholesterol, and cholesterol benzoate of constant specific activities after the second, first, and fourth crystallizations, respectively, as indicated in Tables I and II. It took somewhat longer for the benzoate to reach constant specific activity, presumably because of the presence of benzoic acid in the extract. The specific activities of the residues from the terminal supernatants coincided with that of the crystals. The substrate was added as the dibenzylethylenediamine salt. Rilling and Bloch<sup>10</sup> found no difference in results in squalene formation in yeast from mevalonate as the potassium salt or as the dibenzylethylenediamine salt.

(10) H. C. Rilling and K. Bloch, *J. Biol. Chem.*, **234**, 1424 (1957).

The thin layer chromatographic systems for free sterols do not separate campesterol, stigmasterol,  $\beta$ -sitosterol, and cholesterol. The system for the acetates<sup>9</sup> separates these sterols, although  $\beta$ -sitosterol and campesterol acetates run together. Chromatography of the acetates presented the first evidence that cholesterol was labeled. The gas chromatographic method separates all four sterols, but the cholesterol peak of the plant extract was so small that at first no significance was attached to it.

From the specific activity of the cholesterol acetate of expt 1 it can be calculated that 7300 cpm, or 31% of the total activity of the sterol mixture, was due to cholesterol. No more than 0.075 mg of cholesterol by weight was present in this mixture, and thus the specific activity of cholesterol was at least 97,000 cpm/mg in the native extract. The specific activity of stigmasterol can be roughly estimated at 5000 cpm/mg and, since 1.44 mg of this sterol was present, 7200 cpm or one-third of the total sterol activity can be accounted for by this sterol. Similarly, from expt 2, it can be calculated from the specific activity of cholesterol that 24% of the radioactive counts of the mixture was due to cholesterol. Because of the large amount of endogenous substance, radioactive stigmasterol produced during the course of the experiment has been extensively diluted.

Cholesterol was found in the aqueous phase after defatting with petroleum ether. It became soluble in a nonpolar solvent only after hydrolytic treatment with mineral acid. It is supposed that cholesterol can be conjugated at C-3 and that it may occur as glycoside. It is also possible that cholesterol can be conjugated with sulfuric acid. This speculation is reinforced by the recent findings of cholesterol sulfate in the human organism.<sup>11,12</sup> No other water-soluble conjugate of cholesterol has been discovered in nature.

With the finding of cholesterol in plants,<sup>1-4</sup> increased attention has been drawn to the intermediate role of this substance in plant sterol biosynthesis. Cholesterol comprises but 3% by weight of the total sterol mixture, yet its rate of formation is rapid. One-quarter to one-third of the radioactivity found in all sterols became associated with cholesterol during the incubation period. The high rate of incorporation of label into cholesterol is consonant with the expectation that cholesterol fulfills an intermediary role in formation of other sterols. Data indicate that the turnover rate of cholesterol must be high.

Animals seem to be restricted in their ability to degrade cholesterol, and on a weight basis this compound is the most important of all steroid-nucleus-containing substances. Plants appear to convert cholesterol rapidly to a number of compounds which occur side by side. Bergmann<sup>13</sup> has pointed out that cholesterol has achieved a position of dominance at higher levels of evolution until it has become the principal sterol of vertebrate animals. It remains to be seen whether higher animals have achieved an advantage by limiting the means of biochemical modification of

the steroid side chain. Lipid esters in the circulatory system have been shown to be of advantage when present in excess at C-22, a reaction not rendering the side chain vulnerable with subsequent loss of a ring. This and other transformations may act together to increase solubility. It was pointed out in the water-soluble portion. Conjugation at C-3 and modification may act together to increase efficiency in the ability to transport soluble compounds; this peculiarity is responsible for organic matter at high levels of the sterol.

Reports in the literature that plants arise by a pathway similar to that for animals and yeast. Carotenoids can be incorporated into peas,<sup>14,15</sup> *Ocimum basilicum* matatoes;<sup>16</sup> into stigmasterol in *flora*,<sup>17</sup> and tomatoes;<sup>18</sup> into *Rauwolfia serpentina*,<sup>19</sup> *Dio* *Salvia officinalis* and *S. sclarea* in peas;<sup>20</sup> and into digitoxin and *D. lanata*.<sup>21-23</sup> In several cases, incorporation of carbons or label into sterols has been coincident with the expected location or with the expected <sup>14</sup>C/<sup>12</sup>C ratio. When administered as free compound, leaves of *Digitalis lanata*, digitoxin, digitonin, and diosgenin applied to the surface of *spiculiflora* appears as diosgenin. Bergmann describes an extensive incorporation of <sup>14</sup>C into cholesterol when sterols. The small concentration of all plant sterols in the conversion of cholesterol to cholesterol appears to fulfill the animals: that of key intermediates.

# Communications to the Editor

## Chemical Shift Anisotropies from Nuclear Magnetic Resonance Studies of Oriented Molecules

Sir:

It is now well known that anisotropy in nuclear magnetic shielding can be obtained through measurement of a shift due to partial molecular alignment.<sup>1-3</sup> If the molecule is linear, or if the bond containing the nucleus has an axis of symmetry, it is possible to determine  $\sigma_{\parallel} - \sigma_{\perp}$ , the difference in the shielding for fields parallel and perpendicular to the bond. If the mean shielding constant,  $(\sigma_{\parallel} + 2\sigma_{\perp})/3$ , is also known through measurements on an isotropic sample, both  $\sigma_{\parallel}$  and  $\sigma_{\perp}$  are then available.

Recently the shifts and splittings in the proton and fluorine spectra of  $\text{CH}_2\text{F}$  in *p,p'*-di-*n*-hexyloxyazoxybenzene were observed.<sup>4</sup> It was reported that  $(\sigma_{\parallel} - \sigma_{\perp})^{\text{F}} = -179 \pm 15$  ppm and that the difference in the mean proton shielding parallel and perpendicular to the threefold axis is  $-28 \pm 4$  ppm; if the bond angles are tetrahedral and the CH bonds axially symmetric, the latter result entails  $(\sigma_{\parallel} - \sigma_{\perp})^{\text{H}} = +84 \pm 12$  ppm, a value rightly described<sup>4</sup> as "unexpectedly large." The actual shifts were evidently about  $-195$  cps ( $-2.08$  ppm) and  $-32$  cps ( $-0.32$  ppm) for the F and H resonances.

The purpose of this communication is to point out that a small nmr shift between the nematic and isotropic phases of a liquid crystal solution (relative to an external reference) cannot easily be related to shielding anisotropy. The difficulty is due to shifts arising from the environment of the solute. The isotropic  $\rightarrow$  nematic transition is a first-order phase change, and there is a small decrease in the mean volume susceptibility of the medium leading to a downfield shift. However, there is a more important effect due to the anisotropy in the bulk susceptibility brought about by the more-or-less complete molecular alignment in the nematic phase in the strong magnetic field. If the sample is in a cylinder at right angles to a magnetic field  $H_s$ , the volume susceptibility is  $\chi_{\parallel}$  in the direction of the field, and  $\chi_{\perp}$  at right angles to it, and the field strength inside the cylinder is

$$H_s[1 + 2\pi\chi_{\parallel}]^{-1} \approx H_s\left[1 - 2\pi\chi - \frac{4\pi}{3}\Delta\chi\right]$$

where  $\chi = \frac{1}{3}(\chi_{\parallel} + 2\chi_{\perp})$  is the mean volume susceptibility and  $\Delta\chi = \chi_{\parallel} - \chi_{\perp}$ . In a spherical sample, the field inside is

$$H_s\left[1 + \frac{4\pi}{3}\chi_{\parallel}\right]^{-1} \approx H_s\left[1 - \frac{4\pi}{3}\chi - \frac{8\pi}{9}\Delta\chi\right]$$

The "effective field" acting on a molecule is  $(1 + \frac{4}{3}\pi\chi_{\parallel})$  times the actual field in the medium, so there

(3) For a review, see A. D. Buckingham and K. A. McLauchlan, "Progress in N.M.R. Spectroscopy," Vol. II, L. H. Sutcliffe, J. W. Emsley, and J. Feeney, Ed., Pergamon Press, Oxford, 1967, p 63.

(4) R. A. Bernheim and B. J. Lavery, *J. Am. Chem. Soc.*, **89**, 1279 (1967).

is no bulk susceptibility shielding in a spherical sample, but the equivalent shielding constant in a cylinder is

$$\sigma_b = \frac{2\pi}{3}\chi_{\parallel} = \frac{2\pi}{3}\chi + \frac{4\pi}{9}\Delta\chi$$

The shift  $(2\pi/3)\chi$  is well known,<sup>5</sup> but the second term appears to be new and gives rise to an upfield shift when the solution goes nematic. Measurements of the difference in the field strength needed to produce resonance in a cylinder and a sphere would yield  $\sigma_b$  and hence valuable information about the volume susceptibility.<sup>6</sup>

There are other environmental contributions to the shielding that might change significantly when the medium undergoes the isotropic  $\rightarrow$  nematic transition. In particular, there is the "solvent anisotropy effect,"  $\sigma_a$ ,<sup>7</sup> which arises from the link between the shape of the solvent molecules and their magnetic susceptibilities. Thus in benzene, the large diamagnetic susceptibility in the direction perpendicular to the ring, coupled with the fact that solute molecules can approach a benzene molecule most closely in this direction, leads to a high-field shift of about  $\frac{1}{3}$  ppm.<sup>7</sup> But if the benzene molecules were aligned with the ring planes parallel to the magnetic field, this high-field shift would be converted into a shift  $-\frac{1}{2}\chi_{11}(\chi_{33} - \chi_{11})^{-1}$  times as large, where  $\chi_{11} = \chi_{22}$  is the magnetic susceptibility in the plane of the ring and  $\chi_{33}$  that at right angles to it; this ratio is approximately  $-0.9$  for benzene, and the resulting change in  $\sigma_a$  is about  $-0.6$  ppm.

It is not possible to prescribe definite values for  $\Delta\sigma_b$  and  $\Delta\sigma_a$  in the isotropic  $\rightarrow$  nematic transition in solutions in *p,p'*-di-*n*-hexyloxyazoxybenzene. Although it is apparently a first-order phase change, the decrease in volume, and hence in  $\chi$ , is small and probably less than 1%.<sup>8</sup> However,  $\Delta\chi$  may be about 0.13 ppm (its value for *p*-azoxyanisole<sup>9</sup>) so that  $\Delta\sigma_b \sim +0.18$  ppm. The change in  $\sigma_a$  is doubtless much smaller than that calculated above for benzene, and a figure of  $-0.3$  ppm is reasonable. Thus we would expect a downfield shift when the solvent goes nematic, and this could greatly reduce  $(\sigma_{\parallel} - \sigma_{\perp})^{\text{H}}$ . If it is assumed that  $(\sigma_{\parallel} - \sigma_{\perp})^{\text{H}}$  is zero, the solvent shift is  $-0.32$  ppm and the corrected anisotropy  $(\sigma_{\parallel} - \sigma_{\perp})^{\text{F}}$  is  $-150$  ppm.

From the point of view of evaluating shielding anisotropies, it would seem to be preferable to use an internal reference comprising a molecule of high symmetry; thus  $\text{CH}_4$  would be appropriate for proton spectra, and  $\text{CF}_4$  or  $\text{SF}_6$  for F resonances. Even with internal referencing, special care may be needed in interpreting small shifts, for the change in the environment could affect the solute and reference differently.

# Synthesis of Transition Metal-Monocarbon Carborane Complexes

Sir:

We wish to report the facile synthesis of complexes of the  $B_{10}H_{10}CH^{3-}$  and  $B_{10}H_{10}CNH_2R^{2-}$  ions with several transition metals.<sup>1</sup> The syntheses are based on two general reactions very closely related to the preparative methods recently described for the (3)-1,2-dicarbollyl sandwich complexes:<sup>2,3</sup> (1)  $Na_3B_{10}H_{10}CH$  and anhydrous metal chloride, and (2)  $CsB_{10}H_{12}CH$ , aqueous sodium hydroxide, and metal chloride.

Table I. Analyses

Compound	Calculated, %					Found, %				
	C	H	N	B	Metal	C	H	N	B	Metal
$[(CH_3)_4N]_3Co(B_{10}H_{10}CH)_2$	30.91	10.74	7.72	39.78	10.84	30.99	10.80	7.58	39.73	10.6
$Cs_2Ni(B_{10}H_{10}CH)_2$	4.09	3.78	...	36.84	10.00	3.77	3.90	...	36.55	9.8
$[(CH_3)_4N]_3Fe(B_{10}H_{10}CH)_2$	31.05	10.80	7.78	40.07	10.30	30.92	10.98	7.59	...	9.8
$(CH_3)_4NCo(B_{10}H_{10}CNH_2C_2H_5)_2$	24.83	9.59	8.69	44.70	12.18	25.09	9.63	8.67	...	12.6
$Ni(B_{10}H_{10}CNH_2C_2H_5)_2$	22.01	8.76	6.42	49.45	13.44	22.05	9.08	6.40	...	12.9

The  $B_{10}H_{10}CH^{3-}$  ion is readily prepared as a sparingly soluble sodium salt (I) by deamination and deprotonation of  $B_{10}H_{12}CN(CH_3)_3$  with sodium metal in tetrahydrofuran (THF).<sup>4</sup> Addition of I to a solution of anhydrous  $CoCl_2$  in THF yielded a precipitate of cobalt metal and sodium chloride. The  $Co^{III}(B_{10}H_{10}CH)_2^{3-}$  ion (II) was isolated as either the cesium or tetramethylammonium salt. The salts of II are diamagnetic and yellow [ $\lambda_{max}$  ( $\epsilon$ ): 279 (36,600) and 422  $m\mu$  (382)].

The second type of reaction is illustrated by the synthesis of the  $Ni^{IV}(B_{10}H_{10}CH)_2^{2-}$  ion (III). An aqueous mixture of  $NiCl_2$  (13.5 mmoles),  $CsB_{10}H_{12}CH$  (22.1 mmoles), and sodium hydroxide (270 mmoles) was heated at 40° with air injection for 20 hr. The yellow, diamagnetic cesium salt of III could be isolated in yields as high as 82% from this reaction. By this method one can also obtain good yields of II and salts of the red  $Fe^{III}(B_{10}H_{10}CH)_2^{3-}$  ion (IV).

Preliminary X-ray data on  $Cs_2Ni^{IV}(B_{10}H_{10}CH)_2$  yield the cell parameters:  $a = 20.25$ ,  $b = 12.77$ ,  $c = 14.64$  Å,  $z = 8$ ,  $d(\text{calcd})$  2.08,  $d(\text{found})$  2.04. The  $^{11}B$  nmr spectra of II and III extend over 29 ppm and are grossly similar to one another but have not been completely interpreted. The paramagnetic ion (IV) has a  $^{11}B$  nmr spectrum which extends over approximately 300 ppm and does not appear to show  $^{11}B$ - $^1H$  coupling.<sup>5</sup>

Treatment of  $B_{10}H_{12}CNH_2C_2H_5$  with  $NiCl_2$  in aqueous base gives in good yield, orange, diamagnetic  $Ni^{IV}(B_{10}H_{10}CNH_2C_2H_5)_2$  (V). The mass spectrum of V cuts off sharply at  $m/e$  444 corresponding to the parent ion,  $^{12}C_8^{1}H_{38}^{14}N_2^{11}B_{20}^{62}Ni^+$ . Orange, diamagnetic  $(CH_3)_4NCo^{III}(B_{10}H_{10}CHNH_2C_2H_5)_2$  (VI) was obtained in the same manner. Methylation of V with sodium bicarbonate and methyl iodide gives dark orange

$Ni^{IV}(B_{10}H_{10}NH(CH_3)_2C_2H_5)_2$ . The  $^{11}B$  nmr spectra of these amine derivatives extend over 29 ppm and are similar to those of the unsubstituted complexes but are not as well resolved. Analyses of the compounds are given in Table I.

The striking similarity in properties of the metal complexes reported in this paper and their isoelectronic dicarbollide analogs leads us to suggest that the transition metal in these compounds is  $\pi$ -bonded to the open face of two monocarbon carborane (carbollide) icosahedral fragments. Thus the  $Co^{III}$  species II and VI are apparent analogs of the cobalticinium ion

and the  $Fe^{III}$  species IV analogous to the ferricinium ion. A single crystal X-ray study now in progress should lend support to this postulate.

Salts of the  $(B_{10}H_{10}CH)Mn(CO)_3^{2-}$  and  $Cu^{III}(B_{10}H_{10}CH)_2^{3-}$  ions have also been obtained from  $BrMn(CO)_5$  and copper(II) acetylacetonate, respectively, by the anhydrous route with  $Na_3B_{10}H_{10}CH$ . The  $^{11}B$  nmr spectra of these ions which extend over 20 ppm are similar to one another but dissimilar to the spectra of the nickel and cobalt derivatives.

Further synthetic and structural studies of these new carbollyl-transition metal complexes are in progress and will be reported at a later date.

**Acknowledgment.** The authors wish to thank Mr. J. Nemeth for the microanalyses, Dr. Donald F. Gaines, University of Wisconsin, for the 32-Mc  $^{11}B$  nmr, and the National Science Foundation for support under Grant GP-4982.

## Transition Metal Complexes of $B_{10}H_{10}CNH_2^{3-}$ and $B_{10}H_{10}CH^{3-}$

Sir:

A series of sandwich complexes of transition metals with the  $B_5C_2H_{11}^{2-}$  anion has been reported by Hawthorne and co-workers.<sup>1</sup> These complexes are formally analogous to metallocenes because the metal in both cases is bonded to a pentagonal face which can contribute three bonding molecular orbitals and six electrons.<sup>2,3</sup>

This communication reports the preparation of similar metal complexes of  $B_{10}H_{10}CNH_2^{3-}$  and  $B_{10}H_{10}CH^{3-}$

<sup>a</sup>The presence of water of hydration was established by infrared analysis.

$\text{CH}^{2-}$  by the reactions of  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$ <sup>4</sup> and  $\text{B}_{10}\text{H}_{12}\text{CH}^{4-}$  with transition metal halides under basic conditions.<sup>5</sup> The facile, essentially one-step, preparation of  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$  from decaborane and sodium cyanide makes the  $\text{B}_{10}\text{H}_{10}\text{CNH}_2^{2-}$ -metal complexes particularly accessible;  $\text{B}_{10}\text{H}_{12}\text{CH}^{2-}$  is prepared in two steps from  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$ .<sup>4</sup>

Cobalt, nickel, manganese, and iron complexes have been prepared from both  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$  and  $\text{B}_{10}\text{H}_{12}\text{CH}^{2-}$ ; in addition a chromium complex has been prepared from the latter. These species have the general formulas  $(\text{B}_{10}\text{H}_{10}\text{CNH}_2)_2\text{M}$  and  $(\text{B}_{10}\text{H}_{10}\text{CH})_2\text{M}$ . The over-all charge is dependent on the formal valence of the metal and, for the aminated complexes, also on the degree of protonation of the nitrogen. For example, the complex of Co(III) with the aminated ligand has been isolated as salts of the  $\text{B}_{10}\text{H}_{10}\text{CNH}_2\text{CoB}_{10}\text{H}_{10}\text{CNH}_2^{3-}$  and  $(\text{B}_{10}\text{H}_{10}\text{CNH}_2)_2\text{Co}^-$  anions.

It has been shown<sup>1c</sup> that the  $\text{B}_9\text{C}_2\text{H}_{11}^{2-}$  ligand stabilizes relatively high metal oxidation states; e.g.,  $(\text{B}_9\text{C}_2\text{H}_{11})_2\text{Ni}^{+}$ , which is a Ni(III) complex, can be oxidized to a Ni(IV) species,  $(\text{B}_9\text{C}_2\text{H}_{11})_2\text{Ni}$ . The  $\text{B}_{10}\text{H}_{10}\text{CNH}_2^{2-}$  and  $\text{B}_{10}\text{H}_{10}\text{CH}^{2-}$  ligands also stabilize high oxidation states; in fact, they may be superior to  $\text{B}_9\text{C}_2\text{H}_{11}^{2-}$  in this respect because in their complexes Ni(IV) is the preferred oxidation state (i.e., the isolated products contain Ni(IV) without the need for an additional oxidation step). Furthermore, the yellow-orange, diamagnetic  $(\text{B}_{10}\text{H}_{10}\text{CH})_2\text{Co}^{3-}$  anion, which contains Co(III), is oxidized by ceric ion to an almost black, paramagnetic  $(\text{B}_{10}\text{H}_{10}\text{CH})_2\text{Co}^{2-}$  ion, which formally contains Co(IV). The formal oxidation states in the manganese, iron, cobalt, and chromium complexes as isolated are IV, III, III, and III, respectively. Analyses of representative compounds are given in Table I.

The preparations of the complexes are simple and consist of adding *n*-butyllithium to a mixture of a metal(II) halide (except that  $\text{CrCl}_3$  is used to prepare the chromium compound) and  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$  or a salt of  $\text{B}_{10}\text{H}_{12}\text{CH}^{2-}$  in tetrahydrofuran. An even more convenient preparation of the cobalt and nickel complexes consists of treating  $\text{CoCl}_2$  or  $\text{NiCl}_2$  with  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$  or  $\text{B}_{10}\text{H}_{12}\text{CH}^{2-}$  in aqueous sodium hydroxide. The isolated Fe(III) products are formed by spontaneous air oxidation of the analogous Fe(II) species; oxidation of the other metals to the states observed in the isolated products occurs with concurrent reduction of excess metal halide. The two-electron oxida-

tions ( $\text{M(II)} \rightarrow \text{M(IV)}$ ) may involve both air oxidation and disproportionation.

The iron-, nickel-, chromium-, and cobalt(III) complexes are quite stable in air and are not readily decomposed by acids, consistent with the behavior reported<sup>1</sup> for the  $\text{B}_9\text{C}_2\text{H}_{11}^{2-}$  metal complexes. The manganese complexes decompose slowly in acetonitrile solution; the products have not been identified.

Although the structures of the complexes have not been unequivocally established, it is quite reasonable to assume they are analogous to those of the  $\text{B}_9\text{C}_2\text{H}_{11}^{2-}$  metal sandwich species.<sup>1-3</sup> This assumption is based on the isoelectronic relationship of  $\text{B}_9\text{C}_2\text{H}_{11}^{2-}$  with  $\text{B}_{10}\text{H}_{10}\text{CH}^{2-}$  and  $\text{B}_{10}\text{H}_{10}\text{CNH}_2^{2-}$  and on the chemical similarities noted above for their respective metal complexes. The proposed structure is shown in Figure 1.

Figure 1. Proposed skeletal structure for metal sandwich complexes of  $\text{B}_{10}\text{H}_{10}\text{CH}^{2-}$  and its derivatives

The metal complexes derived from  $\text{B}_{10}\text{H}_{12}\text{CNH}_2$  are of particular interest, not only because of the facile preparation of this aminocarbaborane, but also because the amine group provides convenient access to other C-substituted complexes. For example, the reactions of  $(\text{B}_{10}\text{H}_{10}\text{CNH}_2)_2\text{Ni}$  with nitrous acid and with dimethyl sulfate have given  $(\text{B}_{10}\text{H}_{10}\text{COH})_2\text{Ni}^{2-}$  and  $[\text{B}_{10}\text{H}_{10}\text{CNH}(\text{CH}_3)_2]_2\text{Ni}$ , respectively. An N-alkylated analog,  $(\text{B}_{10}\text{H}_{10}\text{CNH}_2\text{CH}_2\text{C}_6\text{H}_5)_2\text{Ni}$ , has also been pre-

## *endo*- and *exo*-8-Chlorohomotropylum Salts

Sir:

The occurrence of an 8-halohomotropylum ion as an intermediate in the halogenation of cyclooctatetraene is conceivable. It would explain the unique features of this reaction.<sup>1</sup> To provide evidence for this mechanistic possibility, we prepared *exo*- and *endo*-8-chlorohomotropylum salts. von Rosenberg, Mahler, and Pettit<sup>2</sup> obtained stable homotropylum salts by the reaction of cyclooctatetraene with strong acids. Further studies in the laboratories of Winstein<sup>3</sup> and Pettit<sup>4</sup> confirmed the homoaromatic character of the cationic species.

We treated *cis*-7,8-dichlorocycloocta-1,3,5-triene<sup>5</sup> (IA and IB) with antimony pentachloride in dichloromethane at  $-15^\circ$  and isolated the crystalline, colorless *exo*-8-chlorohomotropylum hexachloroantimonate (II,  $X^- = SbCl_6^-$ ) in 95% yield.<sup>6</sup> The salt (mp  $82-85^\circ$  dec in a sealed tube) is stable at room temperature but decomposes on exposure to moist air. Structural assignment is based on the nmr spectrum ( $CD_3NO_2$ ).<sup>7</sup> The homoaromatic protons at positions 2-6 are centered at  $\tau$  1.1 (multiplet); protons 1 and 7 give rise to a triplet at  $\tau$  2.82 with  $J_{12} = J_{18} = 8.2$  cps. The aromatic ring current shifts the triplet of the *endo*-8-H to  $\tau$  8.20.

(6) Satisfactory carbon and hydrogen analyses were obtained.

(7) Determined on a Varian A-60 spectrometer with TMS as internal standard.

Figure 1. Nmr spectrum ( $FSO_3H$ ) of *exo*-8-chlorohomotropylum fluorosulfonate at  $20^\circ$ .<sup>8</sup>

The spectrum corresponds well with that of the homotropylum hexachloroantimonate<sup>2</sup> after making allowance for the effect of the *exo*-8-chlorine. The spectrum of II ( $X^- = FSO_3^-$ ) in fluorosulfonic acid (Figure 1) is very similar.

IA and IB exist at  $-15^\circ$  in a mobile 46:54 equilibrium.<sup>5</sup> Besides  $SbCl_5$  (in  $CH_2Cl_2$  or  $SO_2$ ),  $SnCl_4$  (in  $CH_2Cl_2$ ; II,  $X^- = SnCl_6^-$ )<sup>6</sup> or  $AgSbF_6$  (in  $SO_2$  or  $CD_3NO_2$ ), respectively, also cause chloride elimination from the *exo*,*cis*-dichloride IA to give the *exo*-8-chloro cation II.

In contrast, fluorosulfonic acid attacks the *endo*-dichloro conformer IB. Treatment with  $\geq 4$  equiv of  $FSO_3H$  in  $SO_2$  or with pure  $FSO_3H$  below  $0^\circ$  converted IB to the *endo*-8-chlorohomotropylum salt III ( $X^- = FSO_3^-$ ). Also shown by the nmr spectrum of III (Figure 2<sup>8</sup>) is the equality of vicinal coupling constants, leading to two triplets, one for 1-H and 7-H, the other for 8-H. The  $\tau$  value of *exo*-8-H is shifted by 5.69 to lower field compared with *endo*-8-H in II.

On warming a solution of III in  $FSO_3H$  to  $30.4^\circ$ , a first-order isomerization to the *exo*-chloro cation took

Figure 2. Nmr spectrum ( $FSO_3H$ ) of *endo*-8-chlorohomotropylum fluorosulfonate at  $-40^\circ$ .<sup>8</sup>

(8) TMS is destroyed by  $FSO_3H$ . Chemical shifts were corrected by using the same  $\tau$  values for the two triplets as found for II ( $X^- = SbCl_6^-$ ) in  $CD_3NO_2$ . For mixtures of II and III in  $FSO_3H$ , analogous corrections were applied.

place with a half-life of 37.7 min. Additional kinetic measurements (nmr) at 15.5 and 20.0° furnished values for  $\Delta H^\ddagger$  of 24.4 kcal/mole and for  $\Delta S^\ddagger$  of 3.8 eu. The *exo*-chloride II, probably formed by ring inversion of the *endo*-chloride III, is the thermodynamically stable isomer since no III is detectable after complete isomerization.  $\text{SbCl}_5$  does not catalyze the process  $\text{III} \rightarrow \text{II}$ . Winstein, *et al.*,<sup>3</sup> found a half-life of 19 min for the equilibration of the *endo*-8-*d*-homotropylium ion in  $\text{D}_2\text{SO}_4$  at ca. 32°.

On treating *trans*-7,8-dichlorocyclooctatriene<sup>5</sup> (IV) with  $\text{SbCl}_5$  in dichloromethane at -20°, the *exo*-chloro salt II precipitated. The same reaction in  $\text{SO}_2$  at -40° resulted in a solution of which the nmr revealed solely the presence of II. Interestingly, fluorosulfonic acid at -20° converted IV to the same *exo*-chloro cation II. Thus, in the ionizations of I and IV, induced by  $\text{FSO}_3\text{H}$ , the chloride anion is removed from the *endo* side, while  $\text{SbCl}_5$  gives in both cases the more stable *exo*-chloro cation. The origin of this dichotomy—all ionizations described above are unidirectional and kinetically controlled—is unknown.

Reppe's dichloride V<sup>6</sup> is not transformed to a homotropylium salt by  $\text{FSO}_3\text{H}$ .

## The Halogenation of Cyclooctatetraene via 8-Halohomotropylium Ions

Sir:

The 7,8-*trans*-dihalobicyclo[4.2.0]octa-2,4-dienes which Reppe, *et al.*,<sup>1</sup> obtained from cyclooctatetraene and halogen are the result of multistep reactions.<sup>2,3</sup> In the chlorination, we isolated four isomeric dichlorides and elucidated their structures as well as their mutual relationships.<sup>3</sup> The halogenation shows several unique features: (1) exclusive primary *cis* addition over the solvent range from hexane to acetonitrile; (2) unusually high rate; in the bromination at -55°, the solution remains colorless until the first drop of bromine exceeds 1 mole equiv; (3) the *cis*-7,8-dihalocycloocta-1,3,5-trienes isomerize readily to the *trans* isomers despite steric hindrance of allylic resonance in the tub form.

We propose [8-halohomotropylium cation (II) as an intermediate. The formation of this homoaromatic species would obviously explain the high rate of halogenation. This being the case, both steps of Scheme I, formulated for chlorination, should take place highly

Scheme I

(1) W. Reppe, O. Schlichting, K. Klager, and T. Töpel, *Ann. Chem.*, **560**, 1 (1948).

(2) R. Huisgen and G. Boche, *Tetrahedron Letters*, 1769 (1965).

(3) R. Huisgen, G. Boche, W. Hechtel, and H. Huber, *Angew. Chem.*, **78**, 595 (1966); *Angew. Chem. Intern. Ed. Engl.*, **5**, 585 (1966).

stereoselectively. Experimental evidence on step 2 is easily accessible.

Step 2. We added 1.1 equiv of tetraethylammonium chloride to *exo*-8-chlorohomotropylium hexachloroantimonate (IV)<sup>4</sup> in  $\text{SO}_2$  at -40° and recorded the nmr spectrum of the clear solution. Signals<sup>5</sup> were observed indicating the presence of only *trans*-7,8-dichlorocyclooctatriene (V).<sup>3</sup> Thus, the chloride anion approaches C-1 from the *endo* side.

*cis*-Dichloride III (2.6 mmoles) was treated with 10 mmoles of fluorosulfonic acid in 6 ml of  $\text{SO}_2$  at -20° to give pure *endo*-8-chlorohomotropylium salt (II,  $\text{FSO}_3^-$  instead of  $\text{Cl}^-$ ).<sup>4</sup> After 5 min, 15 mmoles of tetraethylammonium chloride was introduced. The nmr spectrum of the clear solution (-40°, after 10 min) indicated 94% *cis*-dichloride III and 6% *trans* isomer V. The formation of the small amount of V is most likely not due to kinetic, but rather to thermodynamic, control.<sup>6</sup> Thus, both homotropylium ions suffer *endo* attack by the nucleophilic  $\text{Cl}^-$ .

Step 1. Only the *endo*-chlorohomotropylium ion II is consistent with the quantitative formation of the *cis*-dichloride III in the chlorination of cyclooctatetraene. Conclusive evidence for the high stereoselectivity of step 1 ( $\text{I} \rightarrow \text{II}$ ) is not available because with no known chlorinating reagent can the reaction be terminated reliably at the cationic stage II. We assume that  $\text{Cl}_2 \cdots \text{SbHal}_5$  chlorinates faster than  $\text{Cl}_2$  and gives directly 8-chlorohomotropylium hexachloroantimonate. In the reactions with  $\text{Cl}_2$  and  $\text{SbCl}_5$  in dichloromethane, the hexachloroantimonates II ( $\text{SbCl}_6^-$  instead of  $\text{Cl}^-$ ) and IV precipitated and were weighed and analyzed by nmr in  $\text{SO}_2$  at -40°. The use of  $\text{Cl}_2$  and  $\text{SbF}_5$  permitted direct nmr analysis of the clear reaction solutions.

The data of Table I reveal that the yield of *endo*-8-chlorohomotropylium salt rises with decreasing reac-

Table I. Reactions of Cyclooctatetraene with 1.0 Equiv of  $\text{Cl}_2$  and  $\text{SbHal}_5$  in Dichloromethane

tion temperature and increasing concentration of  $\text{SbHal}_5$ ;  $\text{SbF}_5$  appears to be more efficient than  $\text{SbCl}_5$ .

(4) G. Boche, W. Hechtel, H. Huber, and R. Huisgen, *J. Am. Chem. Soc.*, **89** 3344 (1967).

(5) The limit of nmr analysis of the *cis* isomer III in the presence of a large amount of V is ca. 6%.

(6) Uncatalyzed isomerization of the *cis*-dichloride III in  $\text{SO}_2$  at -40° led to 15% V after 30 min and to 40% V after 5 hr.

We interpret these results as concurrent chlorinations by  $\text{Cl}_2$  and reagent VI. The former yields the *cis*-dichloride III which is converted in a second step by  $\text{SbHal}_3$  to give pure *exo*-chloro cation IV.<sup>4</sup> The *endo*-chloro cation II ( $\text{SbHal}_3^-$  instead of  $\text{Cl}^-$ ) can therefore only be the result of a direct attack of the complex VI on cyclooctatetraene. Consistent with this interpretation is the dependence of the ratio II:IV on temperature and  $\text{SbHal}_3$  concentration; this substantiates the conclusion that the primary step of chlorination is the formation of the *endo*-chloro cation II.

On treating cyclooctatetraene with  $\text{D}_2\text{SO}_4$  at  $-10^\circ$ , Winstein, *et al.*,<sup>7</sup> obtained *endo*- and *exo*-8-*d*-homotropylium salt in an 80:20 ratio. Our experiments with  $\text{FSO}_3\text{D}$  at  $-70^\circ$  gave a 75:25 product ratio. The virtually quantitative formation of III in the chlorination requires a more specific *endo* attack of " $\text{Cl}^+$ " on cyclooctatetraene than in the deuteration. Possibly, initial formation of the  $\pi$ -complex I contributes to the high stereoselectivity observed.

***cis-trans* Isomerization.** A 66:34 equilibrium of dichlorides V:III is established in  $\text{CCl}_4$  at  $-30^\circ$  in the presence of alumina.<sup>8</sup> The isomerization III  $\rightarrow$  V in  $\text{SO}_2$  at  $-40^\circ$ <sup>9</sup> is accelerated by catalytic amounts of *p*-toluenesulfonic or fluorosulfonic acid. These observations are also highly suggestive of 8-chlorohomotropylium ions as intermediates. Since ring inversion of *endo*- and *exo*-chloro cation II  $\rightarrow$  IV does not take place at  $-30^\circ$ ,<sup>4</sup> ionization of dichlorides III and V and or  $\text{Cl}^-$  attack on 8-chlorohomotropylium ions II and IV is, therefore, not absolutely stereospecific.

Inspection of models leaves no doubt that the  $\pi$  overlap between the orbitals at positions 1 and 7 of the homotropylium ion is substantially larger on the underside than on the side of the C-8 bridge. This may be the principal reason for the *endo* attack in both steps of Scheme I.

before fragmentation occurs in the vibronically excited state, a rearrangement of some of the molecular ions of VIII occurs to molecular ion c, formally analogous to that of compound XIX, the photoisomer derived from the enone VIII. One pathway by which

the ketene could be lost would be the subsequent fragmentation of this rearranged molecular ion c.

In the high-resolution mass spectrum of the bicyclic photoproduct XIX, the ion formed by elimination of ketene from the molecular ion makes the major contribution (%  $\Sigma$ , 27.47) to the total ion current. The loss of C-2 and C-3 is confirmed in the spectrum of 6,6-dimethylbicyclo[3.1.0]hexan-2-one-3,3- $d_2$ . It appears (see Figures 1 and 2) that the enone VIII generates a hydrocarbon fragmentation pattern primarily via loss of ketene and an oxygen fragmentation pattern by loss of ethylene. Decomposition of the bicyclic-[3.1.0] ketone XIX generates a strikingly similar hydrocarbon fragmentation pattern. Thus, 4,4-dimethyl-2-cyclohexenone may be another example in which rearrangement or fragmentation observed on photon absorption also occurs on electron impact.<sup>12-16</sup>

However, two points remain unexplained in this analogy to the photorearrangement. (a) Compounds I, VI, VII, and XIII, which do lose ketene on electron impact, have been observed not to rearrange on irradiation to the bicyclo system. (b) In addition, comparison of the mass spectrum of cholestenone's photoproduct<sup>17</sup> with that of cholestenone indicates that the "photorearrangement" cannot be the major path under electron impact leading to loss of ketene from cholestenone.

Nonetheless, the bicyclo[3.1.0] system remains an attractive and reasonable general intermediate from which to lose ketene. The bicyclo[3.1.0] system could be generated by any of several bond migrations in the cyclohexenone molecular ion, including the "photorearrangement" VIII  $\rightarrow$  b. Migration to C-3 of a

methyl group from C-4<sup>16</sup> as shown in a  $\rightarrow$  f could lead to formation of the ionized bicyclo[3.1.0]hexan-2-one derivative (f  $\rightarrow$  g) in a manner analogous to that postulated in b  $\rightarrow$  c. In polycyclic systems three different alkyl migrations are possible from the quaternary center  $\gamma$  to the carbonyl group. In VII and XIII

migration of the tertiary  $\gamma$ -hydrogen atom could also lead to a bicyclo[3.1.0]hexan-2-one (a  $\rightarrow$  g). The suggestion is made, then, that ketene is lost from cyclohexenone derivatives through a rearranged bicyclo-[4.1.0]hexan-2-one system, whose formation requires one or another bond migration from the substituted  $\gamma$  carbon.

The structural features reported above are necessary for the loss of ketene from conjugated cyclohexenones, although reports indicate that the relative importance of this elimination may be altered by the presence of additional functional groups<sup>18</sup> and, in the rigid steroid systems, by different stereochemistry.<sup>19</sup>

<sup>a</sup> Isotopically labeled acetanilides had less than 1% random label. The reaction procedure consists of storing a mixture of 1 ml of H<sub>2</sub>O<sub>2</sub> (90%), 1 ml of trifluoroacetic acid, 0.5 ml of chloroform, and 1 mmole of acetanilide at 5° for 5 hr. Dilution of the reaction mixture with water, extraction with ethyl acetate, and paper chromatography of the residue left after evaporation of the solvent produced 1-2% yields of *p*-hydroxyacetanilide. The only other detectable product was *o*-hydroxyacetanilide. <sup>b</sup> Hydroxylated according to B. Brodie, J. Axelrod, P. Shore, and S. Udenfriend, *J. Biol. Chem.*, **208**, 741 (1954). Acetanilide underwent substantial *meta* hydroxylation. Salicylic acid formed both 2,3- and 2,5-dihydroxybenzoic acid. <sup>c</sup> H. Hamilton, J. Hanifin, and J. Friedman, *J. Am. Chem. Soc.*, **88**, 5266 (1966). <sup>d</sup> The random label in this substrate is approximately 2%. Microsomal hydroxylation of this substrate did not lead to significant retention (J. Daly, unpublished results). <sup>e</sup> This is the value obtained after the addition of cold carrier and recrystallization to constant specific activity.

(<sup>2</sup>H, <sup>3</sup>H, Cl, Br, etc.) displaced by the entering hydroxyl migrates to an adjacent position in the aromatic ring.<sup>1-6</sup>

We now wish to report that this novel intramolecular shift occurs also in certain nonenzymatic substitution reactions. Because cationoid intermediates might be expected to facilitate such migrations, a variety of typical electrophilic aromatic substitution reactions were examined. Selectively deuterated and tritiated compounds were prepared either by palladium-catalyzed hydrogenolysis of the corresponding chloro, bromo, or benzoxazolyl ether<sup>7</sup> derivative or, in a few cases, such as the preparation of [*p*-<sup>3</sup>H] toluene, by neutralization of organolithium compounds with deuterium oxide (Table I). Hydrogenolysis of *p*-O-tosyloxyacetanilide

with Raney nickel in the presence of deuterium or tritium led to acetanilide with substantial randomization of label throughout the ring.

The position of the label in the deuterated compounds was ascertained by nmr spectroscopy and the extent of deuterium substitution measured by mass spectrometry. The products of electrophilic substitution from the specifically labeled compounds (Table I) showed no significant retention of deuterium, in agreement with earlier findings on bromination and nitration.<sup>8</sup>

*Of the six nonenzymatic hydroxylating systems examined (Table II), only hydroxylation of [*p*-<sup>3</sup>H]- or [*p*-<sup>3</sup>H]acetanilide by trifluoroacetic acid led to significant migration rather than complete displacement of the *para* substituent.<sup>9</sup>*

Unreacted starting material which was reisolated after the reaction retained the same specific activity and the label was still in the *para* position, since it was lost completely on bromination. The product, [*m*-<sup>3</sup>H]*p*-hydroxyacetanilide, had deuterium in the ring

(8) L. Melander, *Arkiv Kemi*, **2**, 211 (1950).

(9) The migration of a methyl substituent during hydroxylation of prehnitene with trifluoroacetic acid and boron trifluoride in principle provides a precedent and analogy: C. Buehler and H. Hart, *J. Am. Chem. Soc.*, **85**, 2177 (1963).

positions adjacent to the hydroxyl group by comparison of the intensity of the nmr signals of the 3,5-ring protons with those of the 2,6 protons. The retention of tritium (9.6%) and deuterium (7.5%) obtained on *para*-hydroxylation of acetanilide with trifluoroacetic acid may be compared to the retention of tritium (40–50%) and deuterium (15%) in the enzymatic hydroxylation of acetanilide.<sup>5</sup>

Mechanistically, the hydroxylation with trifluoroperoacetic acid is likely to involve attack by "OH<sup>+</sup>" or a related species and presumably proceeds by the pathway

The nature of the oxygenating species involved in the enzymatic hydroxylation of aromatic substrates is still a subject for speculation. The hydroxylating systems of Table II have served as models for the hydroxylases.<sup>10</sup> The degree of retention in other model systems currently under investigation may serve as a useful further guide for the correlation of enzymatic and nonenzymatic hydroxylations.<sup>11</sup>

## Chemical Conversion of Tyrosine to 6-Hydroxyindoles

Sir:

Silver oxide, ferricyanide, and other oxidants convert 3,4-dihydroxyphenylalanine (DOPA), 3-hydroxytyramine, noradrenaline, and related catecholamines to 5,6-dihydroxyindole derivatives.<sup>1</sup> The transformation of tyrosine to 5,6-dihydroxyindole-2-carboxylic acid, however, is only known as an enzymatic reaction and requires *tyrosinase* to effect the initial oxidation to DOPA.<sup>2</sup>

We wish to report the first direct nonenzymatic conversion of methyl or ethyl tyrosinate (I and II, respectively) to the monohydroxyindole VI by the action of

(1) W. L. Dulière and H. S. Raper, *Biochem. J.*, **24**, 239 (1930);

(2) H. S. Raper, *Biochem. J.*, **21**, 89 (1927).

N-bromosuccinimide (NBS). This transformation was discovered when we observed that amino-terminal tyrosine peptides failed to undergo the expected cleavage on treatment with NBS.<sup>3</sup>

When 1.0 mM solutions of the tyrosine esters I–IV in 0.25 M HOAc were treated with aliquots of a 20 mM aqueous NBS solution, the rapid appearance of the characteristic bromo dienone chromophore ( $\epsilon_{260-270} \sim 8000$ ) was observed. This absorption reached a maximum with 3 equiv of NBS on I or II and 1 equiv on the dibromo derivatives III and IV. The bromo dienone V was isolated on a preparative scale from II and from the dipeptides Tyr-Ala and Tyr-Phe. The reactive bromine in V liberated iodine in the starch-potassium iodide test. The analysis accounts for the introduction of three atoms of bromine to give the tribromo dienone hydrochloride V. This remarkable intermediate, which has been discussed previously in connection with the mechanism of cleavage,<sup>4</sup> is apparently stabilized by the ionized amino group in close proximity to the dienone system. In such a labile system, intramolecular Michael addition of the amino group to the dienone would be competitive with the formation of the spirodienone lactone, the reaction underlying the cleavage of peptide bonds.

This was indeed found to be the case. In contrast to the comparatively stable bromo dienone lactone of the tyrosine peptide cleavage,<sup>4</sup> the absorption of the labile dienone V at 260 m $\mu$  on standing decreased slowly, and a new absorption at 320 m $\mu$  began to develop. This absorption reached a maximum with 2 equiv of NBS on esters III and IV and 4 equiv on esters I and II after approximately 16 hr at room temperature or

(3) M. Wilchek and B. Witkop, *Biochem. Biophys. Res. Commun.*, **26**, 296 (1967).

(4) G. L. Schmir, L. A. Cohen, and B. Witkop, *J. Am. Chem. Soc.*, **81**, 2228 (1959).

10-min heating on a steam bath. In all cases identical spectra resulted, indicative of III and IV being intermediates in the reaction of I and II with NBS. Tyrosinamide and tyrosine-N-methylamide gave similar results. Free tyrosine, 3,5-dibromotyrosine, tyramine, and N-acetyl-3,5-dibromotyrosine ethyl ester failed to produce the 320-m $\mu$  chromophore on treatment with NBS.

When the reaction was carried out on a preparative scale, starting with II, IV, or tyrosinamide in 40% aqueous acetic acid, crystalline products were isolated in 20% yield after chromatography on silica (CHCl<sub>3</sub>-CH<sub>3</sub>OH, 9:1). Infrared, ultraviolet, nmr, and mass spectra and elemental analyses suggest the structure of ethyl 5,7-dibromo-6-hydroxyindole-2-carboxylate (VI) or its amide for the 320-m $\mu$  product. The amide [mp 247° dec,  $\lambda_{\max}$  315 m $\mu$  (EtOH)] exhibited a triplet of parent peaks at  $m/e$  331.879, 333.874, and 335.873 in the mass spectrometer consistent with the formula C<sub>9</sub>H<sub>6</sub>N<sub>2</sub>O<sub>2</sub>Br<sub>2</sub> [calcd, 331.88 (<sup>79</sup>Br-<sup>79</sup>Br), 333.879 (<sup>79</sup>Br-<sup>81</sup>Br), and 335.878 (<sup>81</sup>Br-<sup>81</sup>Br)].

The formation of a side product, an unstable red aminochrome,  $\lambda_{\max}$  480 and 320 m $\mu$ , is especially noticeable at pH values above 5. In addition, a colorless, crystalline, indolic compound [ $\lambda_{\max}$  315 m $\mu$  (log  $\epsilon$  4.33), mp 152-155°, C<sub>11</sub>H<sub>10</sub>NO<sub>4</sub>Br,  $m/e$  298.979 and 300.979 (calcd 298.979 and 300.977 for <sup>79</sup>Br and <sup>81</sup>Br)] is obtained from II or IV. The same product, ethyl 5,6-dihydroxy-7-bromoindole-2-carboxylate, was obtained from ethyl 3,4-dihydroxyphenylalanate on oxidation with NBS. NBS in this case converts tyrosine ester to products which as a rule arise only from DOPA.

The dibromoindole VI was reductively debrominated to VII with palladium on charcoal in buffered methanol [mp 169-175°;  $\lambda_{\max}$  (log  $\epsilon$ ) 320 m $\mu$  (4.32), 250 (3.95), 215 (4.28); parent  $m/e$  205.078 (calcd for C<sub>11</sub>H<sub>10</sub>NO<sub>3</sub>, 205.074)]. VII was methylated with dimethyl sulfate in anhydrous acetone containing fused potassium carbonate to give the known ethyl 6-methoxyindole-2-carboxylate (VIII). The ultraviolet spectrum [ $\lambda_{\max}^{\text{EtOH}}$  320 m $\mu$  (log  $\epsilon$  4.28), 250 (3.93), 215 (4.28);  $\lambda_{\min}^{\text{EtOH}}$  265 m $\mu$  (log  $\epsilon$  3.29)] and melting point (132-135°) agree with the reported data.<sup>5</sup>

The low-resolution mass spectrum reveals a parent peak (M) at  $m/e$  219 and principal peaks at 204 (M - CH<sub>3</sub>), 191 (M - CH<sub>2</sub>=CH<sub>2</sub>), 190 (M - C<sub>2</sub>H<sub>5</sub>), 173 (M - C<sub>2</sub>H<sub>5</sub>OH), 158 (M - C<sub>2</sub>H<sub>5</sub>OH - CH<sub>3</sub>), 145 (M - C<sub>2</sub>H<sub>5</sub>OH - CO), 130 (M - C<sub>2</sub>H<sub>5</sub>OH - CH<sub>3</sub> - CO), 119 (M - C<sub>2</sub>H<sub>5</sub>OH - CO - CN), 102 (M - C<sub>2</sub>H<sub>5</sub>OH - CH<sub>3</sub> - 2CO), 76 (M - C<sub>2</sub>H<sub>5</sub>OH - CH<sub>3</sub> - 2CO - CN).

This transformation is now being used for the determination of amino-terminal tyrosine in proteins and for the synthesis of 6-hydroxyindole derivatives.

## Amino Acid Sequence around the Histidine Residue of the $\alpha$ -Lytic Protease of *Sorangium sp.*, a Bacterial Homolog of the Pancreatic Serine Proteases

Sir:

The elucidation of the amino acid sequence of chymotrypsinogen A,<sup>1</sup> chymotrypsinogen B,<sup>2</sup> trypsinogen,<sup>3,4</sup> and, in part, elastase<sup>5</sup> has established that the pancreatic serine proteases are homologous with respect to a subsequence in which two histidines and a cystine residue are components.<sup>6</sup> In chymotrypsin, for example, these components are histidine-40 and -57 and the cystine residue comprised of half-cystine-42 and -58. The discovery of this common structure, in which a disulfide bond could be considered to have the function of bringing the two histidines close together, has prompted several proposals of reaction mechanisms<sup>7-9</sup> which assign a catalytic function to both histidine residues. However, the kinetic evidence implicates only one.<sup>10</sup>

The  $\alpha$ -lytic protease of *Sorangium sp.* is a bacterial protease which is unusual in two respects: it has the same active serine sequence as the pancreatic proteases, i.e., Asp-Ser-Gly-Gly, and it has only one histidine residue.<sup>11-13</sup> The sequences at its three disulfide bridges are under investigation and, in this communication, we report the sequence of a histidylcystine structure which establishes a further homology with the pancreatic enzymes.

The  $\alpha$ -lytic protease, prepared by methods previously described,<sup>14</sup> was digested with pepsin and submitted to the pH 6.5 diagonal procedure of Brown and Hartley.<sup>15</sup> The resulting peptide map is shown in Figure 1. A single peptide (B1) staining for histidine was observed off the diagonal and was paired with a more acidic peptide B2. Peptide B1 stained red and B2 yellow with the cadmium-ninhydrin reagent of Heilmann, *et al.*<sup>16</sup> Peptide B1, after isolation by preparative electrophoresis at pH 6.5, was found to be separable into two histidine peptides, B1A and B1B, by electrophoresis at pH 1.8 (60 v/cm for 60 min). Peptides B1A, B1B, and B2 were subjected to amino acid and sequential analysis from the N-terminal by the "dansyl-Edman" procedure.<sup>17,18</sup> Peptide B1A

was further degraded by digestion with  $\alpha$ -lytic protease (molar ratio 100:1 in 0.05 M N-ethylmorpholine buffer, pH 8.0, for 16 hr at 37°). The resulting peptides (designated as L) were separated by high-voltage electrophoresis at pH 6.5 and 1.8 and subjected to amino acid and sequential analysis. Peptides B1A and B1A3 were also digested with carboxypeptidase to determine C-terminal residues. The results of these analyses are presented in Table I.

The above results assign sequences to peptides B1B and B2 which are compared in Table II with the sequences around histidine-40 and histidine-57 of the pancreatic serine proteases. Within the limits of the comparison, the histidine sequence of the bacterial enzyme shows as much homology with the histidine-57 sequences of the pancreatic enzymes as the latter do with one another; e.g., like trypsin, the bacterial enzyme has six direct matches with the chymotrypsin sequence from residues 52 to 63; in addition, it has a simple reversal of the chymotrypsin sequence at residues 60 and 61. As histidine-57 is the histidine which is alkylated when chymotrypsin<sup>19,20</sup> and trypsin<sup>21</sup> react with their chloromethyl ketone inhibitors, the homology is with sequences around a histidine of proven

significance. The existence of a "histidine loop" in the bacterial enzyme is unproven at present, and peptide B2 is placed on the N-terminal side of peptide

**Figure 1.**

B1B merely for comparison with the C-terminal sequences of histidine-40. Peptide B2 shows no homology with these sequences.

The sequence of subtilisin has been reported recently.<sup>22</sup> Its histidine and active serine sequences are completely different from those of the pancreatic enzymes. The present evidence indicates therefore that bacterial serine proteases have evolved along at least two independent pathways.

### Kinetic Properties of the $\alpha$ -Lytic Protease of *Sorangium* sp.

Sir:

An accompanying communication<sup>1</sup> gives evidence that the amino acid sequence around the only histidine residue of a bacterial protease is homologous with the sequence around histidine-57 of chymotrypsin. This evidence, coupled with previous evidence<sup>2</sup> of homology

Figure 1. Hydrolysis of N-acetyl-L-valine methyl ester in 0.10 M KCl at 25.0°.

around the active serine residue, raises the question as to whether the reaction mechanism of the *Sorangium* enzyme differs in any way from that of chymotrypsin for, if it does not, reaction mechanisms which require chymotrypsin to have two catalytically functional histidines are clearly in need of reappraisal.

The kinetic data reported in this communication are based on measurements of esterase activity in a pH-Stat. The enzyme was prepared by a simplified version<sup>3</sup> of the original procedure. Enzyme concen-

trations were determined from amino acid analyses and the known amino acid composition per mole of enzyme.<sup>4</sup>

Table I gives a comparison of esterase activities toward various N-benzoyl- and N-acetylamino acid esters under reaction conditions which gave initial rates in direct proportion to both the enzyme and the substrate concentration. As the over-all kinetics are Michaelis-Menten kinetics, the second-order velocity constants are designated as  $k_c/K_m$  ratios where  $k_c$  is the catalytic rate constant ( $k_{cat}$ ).<sup>5</sup> It is evident from the range of substrate concentration which gave second-order kinetics that all values of  $K_m$  are greater than 10 mM. An earlier comparison<sup>6</sup> of the enzyme's action pattern on the A and B chains of oxidized insulin had indicated a pancreatic elastase-like specificity for linkages involving the carbonyl groups of neutral, aliphatic amino acids; the specificity shown by Table I is in accordance with these findings.

Table I. Esterase Activities of the  $\alpha$ -Protease at pH 8.0 in 0.10 M KCl at 25.0°

Substrate	[S] <sub>0</sub> , mM	$k_c/K_m$ , M <sup>-1</sup> sec <sup>-1</sup>
Bz-Arg-OEt	11	0.00
Ac-Tyr-OEt	6.3	0.00
Ac-Trp-OMe	2.3	0.00
Bz-Gly-OMe	2.6-10.5	8.07
Ac-Val-OMe	0.60-6.0	16.3

Bz-Ala-OMe	1.02-10.2	723
Bz-D-Ala-OMe	11.0	0.00

\* The enzyme concentration was  $8.0 \times 10^{-8}$  M for Bz-Ala-OMe and  $5.0 \times 10^{-8}$  M for the other esters.

Figure 1 shows the pH dependence of the hydrolysis of N-acetyl-L-valine methyl ester. The values of  $k_c$  and  $K_m$  for this substrate (Table II) were estimated from Eadie plots at higher substrate concentrations. When

Table II.  $K_m$  and  $k_c$  for Hydrolysis of N-Acetyl-L-valine Methyl Ester in 0.10 M KCl at 25.0°

pH	$K_m$ , mM	$k_c$ , sec <sup>-1</sup>
6.30	61 ± 8	0.28 ± 0.01
7.00	72 ± 6	0.94 ± 0.04
8.00	65 ± 4	1.1 ± 0.1

water is replaced by D<sub>2</sub>O, the pK shifts from 6.7 (Figure 1) to 7.35, and  $k_c/K_m$  at the plateau is reduced 2.03-fold. The pH dependence of the hydrolysis of N-benzoyl-L-alanine methyl ester is essentially the same as that shown in Figure 1 (pK = 6.55) although, as indicated in Table I, the value of  $k_c/K_m$  at the plateau is much higher. Activity toward this substrate over the same pH range is unaffected by acetylation of the enzyme with acetic anhydride at pH 6.8 and 0°. The N-terminal alanine residue and the two  $\epsilon$ -amino groups of the enzyme no longer react with 1-fluoro-2,4-dinitrobenzene or with cyanate<sup>7</sup> after this treatment; the electrophoretic mobility of the enzyme at pH 5.0 is reduced by about one-third.

(2) D. R. Whitaker, L. Juráček, and C. Roy, *Biochem. Biophys. Res. Commun.*, **24**, 173 (1966); D. R. Whitaker and C. Roy, *Can. J. Biochem.*, **45**, 911 (1967).

The pH dependence of  $k_c/K_m$  below pH 8 stems from the dependence of  $k_c$ , not of  $K_m$ , on pH (Table II). This pH dependence of  $k_c$ , the pK value of 6.7, its shift to 7.35 by D<sub>2</sub>O, and the one-unit slope of the log  $k_c/K_m$  function all match the data for chymotrypsin and are consistent with a requirement for a single, unprotonated imidazole group.<sup>8</sup> The isotope effect of 2.03 with D<sub>2</sub>O is of the same magnitude as for chymotrypsin and is consistent with general basic catalysis by an imidazole group.<sup>9</sup> The constancy of  $k_c/K_m$  from pH 8 to 10.5 and the activity of the acetylated enzyme indicate that the binding of neutral substrates is completely independent of pH and is not influenced by ionizations of  $\alpha$ - or  $\epsilon$ -amino groups of the enzyme. This represents the only contrast with chymotrypsin, as the latter undergoes a change in conformation at alkaline pH values and loses its ability to bind substrates.<sup>10</sup>

The above comparison thus supports the indications of the direct kinetic evidence for chymotrypsin, *i.e.*, that its reaction mechanism involves only one histidine group.

### Octahedral vs. Trigonal-Prismatic Coordination. The Structure of $(\text{Me}_4\text{N})_2[\text{V}(\text{mnt})_2]^{1-}$

Sir:

It has recently been shown that a large number of uncharged and monoanionic tris complexes of bidentate sulfur donor ligands possess trigonal-prismatic coordination and thus constitute the first examples of nonoctahedral six-coordinate complexes.<sup>2-6</sup> However, prior to this work there has been no unequivocal evidence relating to the structures of the more highly reduced species having charges 2- and 3-. It has in fact been suggested<sup>1</sup> that some of these complexes could be closer to the classical octahedral configuration. In this communication, we report the molecular structure of  $\text{V}(\text{mnt})_2^{2-}$ , which exhibits the first nontrigonal-prismatic coordination geometry for this class of compounds.

Black monoclinic crystals of  $(\text{Me}_4\text{N})_2[\text{V}(\text{mnt})_2]^{1-}$

(6) R. Eisenberg and H. B. Gray, to be published.

(7) The anion was first reported as the  $\text{Ph}_4\text{As}^+$  salt by Davison and co-workers<sup>2</sup> and later isolated using a somewhat different procedure as the  $\text{Ph}_3\text{P}(\text{Me})^+$  salt.<sup>3</sup> The  $\text{Me}_4\text{N}^+$ ,  $\text{Et}_4\text{N}^+$ , and  $\text{Bu}_4\text{N}^+$  salts described

Figure 1. Perspective drawing of the molecular structure of the  $\text{V}(\text{mnt})_2^{2-}$  anion. The cyano groups are omitted.

were grown from acetone-2-propanol solutions. Precession photography revealed systematic extinctions indicating the space group  $\text{C2/c}$  or  $\text{C}_c$ , with a cell of dimensions  $a = 20.53 \text{ \AA}$ ,  $b = 10.19 \text{ \AA}$ ,  $c = 16.98 \text{ \AA}$ ,  $\beta = 124^\circ 15'$  and vol. =  $2935 \text{ \AA}^3$ . The measured density of  $1.37 \pm 0.05 \text{ g cm}^{-3}$  is consistent with four anions and eight cations in the unit cell of calculated density  $1.40 \text{ g cm}^{-3}$ . Assuming the space group  $\text{C2/c}$ , the four vanadium atoms are required to occupy the  $4c$  special positions of the space group and thus the anion is required to have a twofold symmetry axis. This assumption is verified by the satisfactory agreement ultimately obtained.

The intensity data were collected by the multiple film equiinclination Weissenberg technique using  $\text{Cu K}\alpha$  radiation. Intensities were estimated visually and reduced to values of  $F_o$  by standard methods. The structure was solved by standard Patterson, least-squares, and Fourier methods. The  $R$  factor for 88 positional and thermal parameters (allowing the vanadium and three independent sulfurs to have anisotropic temperature factors) is currently 0.125 for 1187 independent nonzero reflections.

A perspective drawing of the coordination geometry is shown in Figure 1; some of the important bond distances are given in Table I. The vanadium lies on a

\* The prime denotes an atom related by the twofold axis.

twofold rotation axis which bisects one of the three ligands. The six sulfur donor atoms are located around the vanadium at an average distance of  $2.36 \pm 0.01 \text{ \AA}$ . The polyhedron described by these sulfur atoms is by no means a regular one, but for some purposes it is usefully described as a very distorted octahedron (*vide supra*). The intraligand S-S dis-

in this study were prepared by a procedure only slightly modified from that given in ref 8.

(8) A. Davison, N. Edelstein, R. H. Holm, and A. H. Maki, *J. Am. Chem. Soc.*, **86**, 2799 (1964).

tances are longer than those of other dithiolate complexes, being  $3.17 \pm 0.01$  (on twofold) and  $3.11 \pm 0.01$  Å for the other two ligands. Analogous distances have been found to be in the range 3.04–3.10 Å in all other structures.<sup>10</sup>

A useful criterion for discussion of coordination geometry in the systems under consideration is the average S–M–S angle involving pairs of donor atoms that are farthest apart. This angle averages  $136 \pm 1^\circ$  in the known trigonal-prismatic structures<sup>2–8</sup> and  $180^\circ$  for the perfect octahedron. However, we must first take into account the constraint imposed upon the idealized octahedron by the rigid nature of the maleonitriledithiolate ligands. Because of this constraint, the average for this angle in the chelated complex derived from an octahedron should be approximately  $173^\circ$ .<sup>11</sup> The average angle found for  $V(mnt)_3^{2-}$  is  $158.6^\circ$ , which is somewhat closer to the “chelated octahedral structure.” The observed distortion is not simply a solid-state phenomenon since the rich electronic spectrum of  $V(mnt)_3^{2-}$  remains essentially identical for various cations ( $Me_4N^+$ ,  $Et_4N^+$ ,  $Bu_4N^+$ , and  $Ph_4As^+$ ) in solid samples and in solutions. Furthermore, the infrared absorptions attributable to the anion are independent of the nature of the cation in solid samples. The distortion must then have an intramolecular electronic origin. We suggest that the two relatively short interligand S–S distances indicate some residual S–S bonding of the type which has been postulated as stabilizing the trigonal-prismatic structure in the uncharged complexes.<sup>2</sup> It is reasonable to expect the additional two electrons in the dianionic complex to cause the ligands to behave more like conventional dithiolates where a “classical” octahedral structure may be favored. Pitting these two effects against the geometric constants of the ligand, we can only say that nature has chosen an interesting compromise configuration; we have much work to do before we can begin to understand its subtleties.<sup>12</sup>

We have recently prepared the  $Ph_4As^+$  salts of  $M(mnt)_3^{2-}$ <sup>13</sup> for  $M = Ti, V, Cr, Mn, Fe, Mo$ ,<sup>14</sup>

(10) (a) This is true for the three prismatic structures,<sup>2–8</sup> the six square-planar structures,<sup>10b–12</sup> and the two dimeric structures<sup>10b,1</sup> which have been fully solved; (b) R. Eisenberg and J. A. Ibers, *Inorg. Chem.*, **4**, 605 (1965); (c) J. D. Forrester, A. Zalkin, and D. H. Templeton, *ibid.*, **3**, 1501 (1964); (d) *ibid.*, **3**, 1507 (1964); (e) C. J. Fritch, Jr., *Acta Cryst.*, **20**, 107 (1966); (f) D. Sartain and M. R. Truter, *Chem. Commun.*, **382**, (1966); (g) R. Eisenberg, Z. Dori, J. A. Ibers, and H. B. Gray, to be published; (h) J. M. Enemark and W. N. Lipscomb, *Inorg. Chem.*, **4**, 1729 (1965); (i) M. J. Baker-Hawkes, Z. Dori, R. Eisenberg, and H. B. Gray, to be published.

(11) For comparison, in  $Cr(C_2O_4)_3^{2-}$ , where the average “bite” O–Cr–O angle is  $82^\circ$ , we have calculated the average (largest) O–Cr–O angle to be  $172^\circ$  [J. N. van Niekerk and F. R. L. Schoenig, *Acta Cryst.*, **5**, 499 (1952)].

(12) For example, the V atom lies significantly out of the planes determined by the ligands alone. Pertinent geometrical parameters (such as interligand dihedral angles) determined solely from the  $MS_n$  framework tend toward octahedral structure whereas related parameters set by the ligand planes suggest structure closer to trigonal prismatic. This finding may indicate that the ligand unit “prefers” the prism structure whereas the metal is desirous of octahedral coordination. Another interesting result arises on comparison of the C–C bond lengths in this structure with corresponding parameters from the  $V(S_2C_6Ph)_3$  structure.<sup>14</sup> The pertinent distances for  $V(mnt)_3^{2-}$  are  $1.37 \pm 0.02$  (two distances related by twofold axis) and  $1.29 \pm 0.03$  Å, whereas the corresponding distances for  $V(S_2C_6Ph)_3$  are  $1.38 \pm 0.01$  and  $1.46 \pm 0.02$  Å. The drastic shortening of one C–C bond (from 1.46 to 1.29 Å) suggests that the ligands do not participate equally in the two-electron reduction described by  $VL_2 + 2e \rightarrow VL_2^{2-}$ .

<sup>a</sup> Cation is  $Ph_4As^+$ . Magnetic moments are for solid samples at room temperature. <sup>b</sup> Details reported in ref 13. <sup>c</sup> From ref 8.

W,<sup>14</sup> and Re. We find that the Ti, V, and Cr complexes have nearly identical X-ray powder patterns and thus appear isomorphous. It is also interesting to note the magnetic properties of these first-row complexes. If the ligands are considered to be dianions, then the central metal is in the formal IV oxidation state and the moments are found to be those typical of low-spin octahedral compounds (see Table II). Furthermore, spectral studies indicate a certain similarity in the electronic structures of the complex anions. In view of the evidence, then, we suggest that all the first-row  $M(mnt)_3^{2-}$  complexes have distorted octahedral structures. Thus, the picture seems to be emerging that the more highly reduced species will approach the classical octahedral stereochemistry, while the oxidized forms will invariably possess the unusual trigonal-prismatic coordination.

29 (1966). The magnetic results reported initially by these authors for the Mn and Fe compounds are apparently in error; our results are in agreement with their latest values (J. A. McCleverty, private communication).

## Chronology in Photochemical Mechanisms.

### The Reaction of

### 6-Phenyl-6-*p*-cyanophenylbicyclo[3.1.0]hex-3-en-2-one. Mechanistic Organic Photochemistry. XXV<sup>1</sup>

Sir:

One of the most challenging questions in photochemistry concerns the chronology in photochemical reaction mechanisms. In particular, one would like to know at which point in a transformation electronic excitation is lost.

In the type B rearrangement<sup>2</sup> of 6,6-disubstituted bicyclo[3.1.0]hex-3-en-2-ones the first step seems without doubt to be fission of bond 2–4 (cyclohexane numbering; see Chart I) of the triplet<sup>3</sup> excited state ( $1^*$ ) of the bicyclic ketone; fission of this internal three-ring bond converts carbons 2 and 4 to valency-deficient centers to which aryl (or alkyl in nonaryl cases) migration might occur. However, the migration to C-2 and C-4 could occur immediately following bond 2–4 fission and therefore be a reaction of a triplet excited state (e.g.,  $2^*$ ), or

(1) For paper XXIV see H. E. Zimmerman, R. W. Binkley, R. S. Givens, and M. A. Sherwin, *J. Am. Chem. Soc.*, in press.

(2) See H. E. Zimmerman, *Science*, **153**, 837 (1966).

(3) Evidence for involvement of the triplet has been presented by H. E. Zimmerman, R. Keese, J. Nasielski, and J. S. Swenton, *J. Am. Chem. Soc.*, **88**, 4895 (1966).

instead might follow electron demotion and thus be a reaction of the ground-state zwitterion 2. The latter mechanism is the one proposed by us earlier<sup>4</sup> to account for the products of the type B process.

**Chart I<sup>a</sup>**

<sup>a</sup> Processes ruled out, — — —.

An approach likely to provide the answer involved the study of the photochemical behavior of 6-phenyl-6-*p*-cyanophenylbicyclo[3.1.0]hex-3-en-2-one (1). If the electronically excited state 2\* rearranges after 2,4-bond fission, then *p*-cyanophenyl migration should be preferred. Such a result would be in accord with Rüchardt's finding of a strong preference (19:1 to 35:1) for cyanophenyl over phenyl migration in free-radical rearrangements.<sup>6</sup> Additionally, such a result would have analogy in our earlier studies of excited-state migratory aptitudes; here the excited states of 4-phenyl-4-*p*-cyanophenyl-1(4H)-naphthalenone (8) and 4-phenyl-4-*p*-cyanophenylcyclohexenone (9) were shown to undergo a preferred *p*-cyanophenyl migration (2.2:1 for 8\*; 15:1 for 9\*) to the  $\beta$  carbon of the excited enone moiety.<sup>6,7</sup>

On the other hand, if the ground-state zwitterion

(6) H. E. Zimmerman, R. C. Hahn, H. Morrison, and M. C. Wani, *J. Am. Chem. Soc.*, **87**, 1138 (1965).

(7) H. E. Zimmerman, R. D. Rieke, and J. R. Scheffer, *ibid.*, **89**, 2033 (1967).

rearranges, preferential phenyl migration should ensue since phenyl bearing an electron-withdrawing group as cyano should not migrate readily to a cationic center.

6-Phenyl-6-*p*-cyanophenylbicyclo[3.1.0]hex-3-en-2-one (1) was prepared by a synthesis involving irradiation of 4-phenyl-4-*p*-cyanophenylcyclohexadienone (10) and affording both epimers of 1.<sup>8</sup>

The results of irradiation of 6-phenyl-6-*p*-cyanophenylbicyclo[3.1.0]hex-3-en-2-one (1) are collected in Table I. The first striking observation noted is that irradiation of either stereoisomer of 1 gives the *same* distribution of phenolic products, with the 2,3-diarylphenol predominating over the 3,4 isomer, as was the case for the diphenyl analog. Additionally, it was found that on short irradiations recovery of bicyclic ketone gave only the stereoisomer used as reactant. Thus there is evidence for a species common to both reactant stereoisomers in which the internal three-ring bond is broken and memory of the reactant stereochemistry is lost. Furthermore, once this central bond is broken, there is no reclosure; such reclosure would afford a mixture of bicyclic ketones. Other three-ring bond openings followed by free rotation are similarly precluded.

Secondly, there is a dramatic contrast between the previously studied cases where cyanophenyl migrates in preference<sup>6,7</sup> and the present reaction where only phenyl migration is observed. Thus, mainly 2-phenyl-3-*p*-cyanophenylphenol (6) and smaller quantities of 3-*p*-cyanophenyl-4-phenylphenol (7) were found. No *p*-cyanophenyl migration products could be detected. The preferred phenyl migration provides strong support for zwitterion 2 being the species undergoing aryl migration, and electron demotion thus occurring prior to the migration. We note that it is insufficient to select one group as migrating preferentially in photochemical reactions; one must inspect the details of the reaction and determine at which stage migration occurs. In the present instance of the type B rearrangement the scheme

(8) Synthetic details and structure proofs will be reported in our full paper in press. All new compounds were properly characterized and acceptable elemental analyses were obtained.

in Chart I rationalizes the information<sup>9</sup> that the triplet excited state<sup>10</sup> of product is not reached.

**Acknowledgment.** Support of this research by a National Science Foundation Predoctoral Fellowship for J. O. G. and by an Army Research Office (Durham) grant is gratefully acknowledged.

(9) The demotion is shown as occurring just subsequent to internal three-ring bond fission with  $2^*$  pictured as a discrete species; this is a convenience. Thus  $2^*$  may not be an energy minimum, and demotion may occur by crossing or close approach of potential energy surfaces<sup>3</sup> and change in configuration at a slightly earlier or later point in the transformation.

(10) The intervention of the triplet in the phenol-forming reactions is suggested by the formation of the same products in the photosensitized runs as in the direct runs and by analogy to the diphenyl analog<sup>3</sup> where the phenolic product was shown to arise from the triplet and the acidic product from triplet and singlet.

## Molecular and Electronic Structure of Pentacyanocobaltate<sup>1</sup>

Sir:

The complex  $\text{Co}(\text{CN})_5^{2-}$  has occasioned a good deal of interest in late years. Its action as a hydrogenation catalyst<sup>2</sup> for certain unsaturated organic molecules and the kinetics of its free-radical type reactions with some organic halides<sup>3,4</sup> have been subjects of recent

Figure 1. Electron spin resonance spectra for  $\text{Co}(\text{CN})_5^{2-}$  in 2:1 ethylene glycol-water: upper curve, 300°K; lower curve, 77°K in frozen solution. Spectra in pure ethylene glycol are not significantly different.

investigation. ESR and optical spectral studies<sup>5,6</sup> of oxidation products of  $\text{Co}(\text{CN})_5^{2-}$  have also been carried out.

Up to now, the geometry of  $\text{Co}(\text{CN})_5^{2-}$  in solution has been unknown; supposing it to be five-coordinate, the two most likely idealized spatial arrangements are the trigonal bipyramid (of  $D_{3h}$  symmetry) and the square pyramid (of  $C_{4v}$  symmetry). (This latter symmetry would also hold if weak axial solvation made the complex six-coordinate.)

Figure 2. Partial diagram of electronic energy levels and suggested ground state for square-pyramidal  $\text{Co}(\text{CN})_5^{2-}$ .

We have measured optical and esr spectra of pentacyanocobaltate(II) under a variety of conditions; here we show how the data from these experiments point to an idealized square-pyramidal ground-state geometry for this system.

Solutions for esr spectra were prepared by dissolving  $\text{K}_3\text{Co}(\text{CN})_5 \cdot 4\text{H}_2\text{O}$  in 2:1 ethylene glycol-water and in pure ethylene glycol. Examination of the optical spectra of these solutions at 300°K and frozen at 77°K reveals the absorption pattern characteristic of the paramagnetic ( $S = 1/2$ ), monomeric  $\text{Co}(\text{CN})_5^{2-}$  species.<sup>7</sup> In particular, the intensity of the band peaking at 10,350  $\text{cm}^{-1}$  shows  $\text{Co}(\text{CN})_5^{2-}$  to be the predominant species under the conditions of our experiment at 77°K. Confirmation of the existence of  $\text{Co}(\text{CN})_5^{2-}$  in the frozen solutions was necessary in light of results which indicate that dimerization and oxidation may readily occur under these conditions.<sup>5,6</sup>

Figure 1 shows esr spectra for  $\text{Co}(\text{CN})_5^{2-}$  at 300 and 77°K. At 300°K, a broad resonance lacking hyperfine structure and centered at  $g = 2.11 \pm 0.01$  is seen. On freezing the solution at the lower temperature, the pattern observed is a 16-line resonance expected from an axially symmetric  $^{59}\text{Co}$  ( $I = 7/2$ ) species, with two of the  $g_{\parallel}$  lines hidden under the second and fifth lines of the  $g_{\perp}$  pattern. Analysis of this spectrum gives  $g_{\parallel} = 1.992 \pm 0.005$ ,  $g_{\perp} = 2.157 \pm 0.005$ , and hyperfine tensor components  $A = 87 \pm 2$  and  $B = 28 \pm 2$  gauss.

The axial symmetry of the  $g$  tensor combined with the value of 1.992 for  $g_{\parallel}$  strongly suggest a square-pyramidal structure for  $\text{Co}(\text{CN})_5^{2-}$  with the unpaired electron placed in an orbital of  $d_{xy}$  symmetry ( $^2A_1$  ground state). This is nicely compatible with the electronic energy levels expected for a square-pyramidal pentacyano complex (Figure 2). The ground state in a  $d^7$  case would be  $(e')^4(b_2)(a_1)^1 = ^2A_1$ . Furthermore, none of the ground-state possibilities in a trigonal-bipyramidal geometry is consistent with the esr results.<sup>9</sup>

The electronic spectrum of  $\text{Co}(\text{CN})_5^{2-}$  in aqueous solution shows<sup>8</sup> bands at 10,350  $\text{cm}^{-1}$  ( $\epsilon$  233), 16,200 (7), 23,300 (65), 31,700 (527), 35,700 (4030), 38,100 (980 sh), and 43,300 (6500). The rich pattern of weak-

(7) A. W. Adamson, *J. Am. Chem. Soc.*, **73**, 5710 (1951).

(8) Our electronic spectral measurements are in essential agreement with those reported by N. K. King and M. E. Winfield, *ibid.*, **73**, 3366 (1951).

(9) The ground state  $(e')^4(e')^1 = ^2E'$  expected for  $D_{3h}$   $\text{Co}(\text{CN})_5^{2-}$  should give  $g_{\parallel} \gg 2.0$ . The fact that a slight Jahn-Teller distortion would be expected does not affect this conclusion.

and medium-intensity absorptions, especially in the 10,000–25,000-cm<sup>-1</sup> range, again points to a system of electronic levels appropriate for a square-pyramidal Co(CN)<sub>5</sub><sup>3-</sup>. At least two reasonable assignment schemes exist based on the splitting diagram shown in Figure 2.<sup>30</sup> Contrariwise, simple extrapolation of electronic levels from analogous trigonal bipyramidal complexes indicates that an approximately D<sub>3h</sub> Co(CN)<sub>5</sub><sup>3-</sup> would not exhibit electronic bands between 8000 and 20,000 cm<sup>-1</sup>.<sup>11</sup> Thus, the combined esr and optical spectral data require a square-pyramidal structure for Co(CN)<sub>5</sub><sup>3-</sup> in solution.

(10) We tentatively suggest the following assignments: 10,350 cm<sup>-1</sup>, <sup>1</sup>A<sub>1</sub> → <sup>1</sup>B<sub>1</sub> (x<sup>2</sup> → x<sup>2</sup> - y<sup>2</sup>); 16,200 cm<sup>-1</sup>, doublet → quartet; 23,300 cm<sup>-1</sup>, <sup>1</sup>A<sub>1</sub> → <sup>1</sup>B<sub>2</sub> (xy → x<sup>2</sup>); 31,700 cm<sup>-1</sup>, <sup>1</sup>A<sub>1</sub> → <sup>1</sup>A<sub>2</sub> (xy → x<sup>2</sup> - y<sup>2</sup>). The intense bands at 35,700 and 43,300 cm<sup>-1</sup> probably represent allowed M → π\*(CN<sup>-</sup>) transitions.

(11) The observed ligand field bands in trigonal bipyramidal Ni[PPh(OR)<sub>2</sub>](CN)<sub>3</sub> complexes (B. B. Chastain, R. Pruett, E. A. Rick, and H. B. Gray, to be published) are at approximately 25,000 and 29,000 cm<sup>-1</sup>. In addition, there is very little difference in the positions of the lowest ligand-field bands in Ni(CN)<sub>5</sub><sup>3-</sup> and Ni[PPh(OR)<sub>2</sub>](CN)<sub>3</sub>. Thus, we may expect a trigonal bipyramidal Co(CN)<sub>5</sub><sup>3-</sup> to have an e' → e' band below 8000 cm<sup>-1</sup> and an e' → a<sub>1</sub>' band at about 25,000 cm<sup>-1</sup>.

## Direct Evidence for the Formation of Diphenylmethyle in the Photolysis of Triphenyl- and Tetraphenyloxirane

Sir:

Recent studies have shown that the photolytic reactions of oxiranes can give rise to products which have been interpreted in terms of carbene (methylene) intermediates.<sup>1</sup> We wish to report convincing direct evidence for the formation of diphenylmethyle (III) in the photolysis of triphenyloxirane (I) and of tetraphenyloxirane (II) (Scheme I).

Scheme I

Irradiations were carried out in methylcyclohexane glass at 77°K. Typically, a solution (10<sup>-4</sup> M) of the oxirane was irradiated<sup>2</sup> with 2537-Å light for 5–30 sec. The photolysis products were identified by a combination of epr and luminescence techniques.

The total luminescence spectrum<sup>3</sup> obtained after II

Soc.*, **88**, 1579 (1966); (c) H. Kristinnson, *Tetrahedron Letters*, 2343 (1966); (d) H. Kristinnson, R. A. Mateer, and G. W. Griffin, *Chem. Commun.*, 415 (1966); (e) G. W. Griffin and co-workers, unpublished work.

(2) An air-cooled Rayonet Chamber Reactor (Southern New England Ultraviolet Co., Middletown, Conn.) was used as the light source equipped with 16 8-w low-pressure mercury lamps.

Figure 1. Photolysis of tetraphenyloxirane: luminescence of products.

was irradiated is shown in Figure 1. By use of a phosphoroscope it was possible to show that part of this luminescence was phosphorescence which corresponded closely with that of benzophenone, and the remaining luminescence was identified as the fluorescence previously reported for diphenylmethyle (III).<sup>4</sup>

Further confirmation for the presence of III was obtained from epr studies. The epr absorption spectrum of the same photolyzed solution which had been used in the luminescence measurements was attributed to a ground-state triplet molecule with zero-field parameters  $D/hc = 0.4053$  cm<sup>-1</sup>,  $E/hc = 0.0190$  cm<sup>-1</sup>. The comparable values for these parameters which had been obtained for III (in benzophenone) are: (a) randomly oriented sample:<sup>5</sup>  $D/hc = 0.4055$  cm<sup>-1</sup>,  $E/hc = 0.0194$  cm<sup>-1</sup>; and (b) single crystal:<sup>6</sup>  $D/hc = 0.40505$  cm<sup>-1</sup>,  $E/hc = 0.01918$  cm<sup>-1</sup>.

When a solution of I was photolyzed, the phosphorescence of benzaldehyde was detected as well as the fluorescence of III. The epr of III was detected with zero field parameters  $D/hc = 0.4056$  cm<sup>-1</sup>,  $E/hc = 0.0188$  cm<sup>-1</sup>. However, no epr absorption signals corresponding to those of phenylmethyle<sup>7</sup> were detected and no phosphorescence which could be ascribed to benzophenone was observed. This is to be contrasted with the results obtained in solution where products which could be derived from both phenyl- and diphenylcarbene were observed.<sup>1a</sup>

(3) The luminescence spectra were recorded on an Aminco-Kiers spectrophotofluorometer (American Instrument Co., Silver Spring, Md.).

(5) A. M. Trozzolo, E. Wasserman, and W. A. Yager, *J. Chim. Phys.*, **61**, 1663 (1964); E. Wasserman, A. M. Trozzolo, W. A. Yager, and R. W. Murray, *J. Chem. Phys.*, **40**, 2408 (1964).

(6) R. W. Brandon, G. L. Closs, and C. A. Hutchison, Jr., *ibid.*, **37**, 1878 (1962); R. W. Brandon, G. L. Closs, C. E. Davoust, C. A. Hutchison, Jr., B. E. Kohler, and R. Silbey, *ibid.*, **43**, 2006 (1965).

(7) A. M. Trozzolo, R. W. Murray, and E. Wasserman, *J. Am. Chem. Soc.*, **84**, 4990 (1962).

The effects of variations in wavelength and irradiation times also are noteworthy. Both I and II do not absorb light having a wavelength greater than 3000 Å. However, when the sample was irradiated for only a short time (~5 sec) with 2537-Å light, cleavage occurred with the production of III and the corresponding carbonyl compound (IV or V), and subsequent irradiation with 3500-Å light caused further photolysis, suggesting that sensitization was occurring. Photosensitizers such as benzophenone and acetophenone appeared qualitatively to give increased yields of III over those obtained in unsensitized photolyses. Such effects had not been observed earlier in previous work in solution.<sup>1a</sup>

These experimental data, besides confirming the previous postulation that methylene intermediates may be produced upon photolysis of oxiranes, also show that oxiranes provide another set of precursors for the epr study of methylenes, in addition to the diazo compounds<sup>8</sup> and bisazides<sup>9</sup> which have been used previously.

The mechanism by which the methylene is formed in the photolysis of these oxiranes is of some interest. The present work does not exclude a two-step homolytic process such as that formulated in Scheme II.

Scheme II

However, in epr studies in the magnetic field region where monoradicals or triplets with smaller spin-spin interaction (such as would be anticipated for VI) might exhibit resonance absorption, only a relatively weak signal was observed. Thus, one is tempted to conclude that if VI or VII is formed in a rigid glass, it has a rather short lifetime, and either reverts to II or fragments to III and V. Furthermore, in view of recent observations<sup>10</sup> on the solvolytic photochemical cleavage of cyclopropanes (a reaction which competes with the fragmentation to carbene) we should consider an ionic intermediate perhaps formed by initial heterolytic cleavage or in a later step from VI or VII. Further studies on the mechanism of the photolysis of oxiranes are continuing.<sup>11</sup>

(11) NOTE ADDED IN PROOF. According to P. Petrellis (unpublished results), diphenylcarbene is formed also in the photolysis of 2-methoxy-2,3,3-triphenyloxirane. The carbene was trapped in methanol as the methyl ether of benzhydrol. Methyl benzoate, the accompanying fragment, was isolated by glpc and compared with authentic material. The presence of III was detected by epr and luminescence studies. These data confirm and are consistent with the results of T. I. Ternikova and I. P. Stepanov, *Zh. Organ. Khim.*, **2**, 1525 (1966); *Chem. Abstr.*, **66**, 54820j (1967).

## Inversion of Positional Reactivity Mechanisms of Hydrogen-Deuterium Exchange for Pyridine

Sir:

Considerable confusion in the positional reactivity order has been reported for pyridine. Relative rates at positions 4, 3, 5, and 2, 6, 10<sup>3</sup>, and 1, respectively, in these deprotonations were said to be an anionic intermediate resulting from the amide ion to substrate. By reported not to exchange in I (220°) exclusive deprotonation said to result.<sup>1,2</sup>

We wish to present a change for pyridine. We have observed inversion in the relative positional reactivity in aqueous solution and for the mechanisms of deprotonation. Pyridine undergoes exchange at meta and 2,6 positions. In NaOD the exchange, but in the order 4 >

For kinetic runs in acidic solutions of DCl were mixed, and heated (218°). Analysis of nmr showed exchange only pseudo-first-order rate constants are expressed as a function of the resulting curve indicates at position 2 or 6 increase protonated pyridine increases and approaches that in neutral pyridine that the mechanism for this of deuterioxide ion on pyridine. This ylide then captures deuterated pyridine (path 1). found in separate experiments in pyridine chloride in D<sub>2</sub>O. At 2

(2) Y. Kawazoe, M. Ohnishi, and T. Kikuchi, *J. Org. Chem.*, **29**, 1384 (1964).

(3) We are unable to repeat these results.

(4) Although deprotonation takes place at positions 2 and 6, for example, all rate constants for deprotonation at a single position are consistent with a single kinetic treatment of consecutive, first-order reactions.

that the rate constant, *k*, for reaction expression in [(H-2, H-6) + (H-2, D-2)] concentration ratio in this expression was

(5) That log [pyridine]/[pyridinium ion] + p*K*<sub>a</sub>. The p*K*<sub>a</sub> value is known from conditions of our experiments, but the rate is accurately known from the conditions employed.

Figure 1. Log-log plot for the rate of hydrogen-deuterium exchange for pyridine at positions 2,6 in  $D_2O$  at  $218^\circ$  as a function of acidity. Left ordinate gives the ratio of the rate of exchange in pyridine-pyridinium ion mixtures to the rate of exchange in neutral water. Right ordinate indicates the observed rate constant. Total concentration of pyridine in all forms is 1.1 M.

occurs at only the 2,6 positions and is inhibited by decreasing the deuterioxide ion concentration.<sup>6</sup>

There is considerable precedent for ylide I. Such an intermediate is said to result during the decarboxylation of pyridine-2-carboxylic acid and of the betaine N-methylpyridine-2-carboxylic acid.<sup>7</sup> The dipolar intermediates which result during similar decarboxylations have been trapped.<sup>8,9</sup>

In another series of experiments pyridine and  $D_2O$ -NaOD were heated in a Monel bomb ( $198 \pm 3^\circ$ ).<sup>10</sup> Pyridine, recovered in good yield, was analyzed for positional deuterium content by nmr using *t*-butyl alcohol as an internal standard. Rates of exchange at all positions showed dependence on deuterioxide ion concentration. At low base concentrations the rates of exchange at position 2 were much greater than at 3 or 4. At high base concentration, in contrast, the 4 position exchanged most rapidly, followed by 3, and then 2. Rate constants for each position are compared by a graphical method in Figure 2. A slope in these plots gives the ratio of rate constants for exchange at two positions.<sup>11</sup> Such a plot for the rate of exchange at position 4 vs. exchange at 3 has a slope of 1.3; therefore,  $k_4/k_3$  is 1.3. Data from several

(6) Another possible mechanism, in which pyridine removes a proton from a C-H center of a pyridinium ion, can be eliminated by the shape of the pD-rate curve. This mechanism demands a rate maximum when [pyridine] and [pyridinium ion] are equal. This maximum is not observed.

(11) S. Benson, "The Foundations of Chemical Kinetics," McGraw-Hill Book Co., Inc., New York, N. Y., 1960, pp 98-99.

Figure 2. Log-log plot for the rate of hydrogen-deuterium exchange for pyridine in  $D_2O$ -NaOD at  $198^\circ$ . The ordinate expresses the inverse mole fraction of hydrogen remaining in either the 2,6 (circles) or 4 (squares) positions and the abscissa gives the inverse mole fraction of hydrogen remaining in the 3,5 positions. Approximate half-life for position 2 in 1.0 M NaOD is 0.9 hr.

determinations at different base concentrations were employed. Similarly  $k_3/k_2$  is 2.3. For this latter comparison only data from runs in 1 N NaOD were used in order to minimize the effect of reaction at positions 2,6 by path 1. Relative rates of exchange of unprotonated pyridine at positions 4, 3, and 2 are 3.0, 2.3, and 1.0, respectively.

There can be little doubt about the positional reactivity order of base-catalyzed exchange for pyridine. We have found a similar order in *t*-butyl alcohol and in methanol at much lower temperatures. Exchange in liquid ammonia also follows the same pattern.<sup>1</sup> Furthermore, the rate of exchange for 3-chloropyridine at position 4 is much greater than at 2 in both methanol and liquid ammonia.<sup>12</sup>

The mechanism for exchange in basic solution most likely involves removal of a proton from pyridine by deuterioxide ion. The resultant pyridyl anion then abstracts a deuteron from solvent to form exchanged product (path 2). This mechanism is similar to that for exchange of chloropyridines in  $CH_3OD$ - $CH_3ONa$  or  $NH_3$ - $NaNH_2$ .<sup>13</sup>

That two pathways exist for exchange at position 2 while only one mode is dominant for positions 3 or 4 is readily understandable. Zwitterionic intermediates which would result from deprotonation of a pyridinium ion at position 3 or 4 have much less coulombic stabilization than ylide I.<sup>13</sup>

# An Unexpected Product in the Reaction of

$\text{PtHCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  with  $\text{C}_2\text{F}_4$ .

The Structure of the  $\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2^+$  Cation and Evidence for the Existence of the  $\text{SiF}_6^-$  Ion

Sir:

In a recent paper<sup>1</sup> one of us described the reaction of *trans*- $\text{PtHCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  with  $\text{C}_2\text{F}_4$  and postulated that one of the low-yield products isolated was a reaction intermediate,  $\text{PtHCl}(\pi\text{-C}_2\text{F}_4)(\text{P}(\text{C}_2\text{H}_5)_3)_2$ . We now report that studies of this compound by X-ray diffraction techniques, and further chemical characterization, have not confirmed the structure postulated. The compound is now known to contain the new cation *trans*- $\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2^+$ , which is isoelectronic with Vaska's compound<sup>2</sup>  $\text{IrCl}(\text{CO})(\text{PR}_3)_2$ , where R may be alkyl or aryl. We present evidence here that the anion is  $\text{SiF}_6^-$  when the reactions are carried out in silica tubes, and that both  $\text{SiF}_6^-$  and  $\text{BF}_4^-$  are formed when reactions are carried out in Pyrex glass tubes. The formation of  $\text{SiF}_4$  as a by-product had been noted previously,<sup>1</sup> indicating attack by HF on the glass walls of the reaction vessel, but apparently the glass is degraded more thoroughly than had been thought.

A sample of the compound isolated from reactions in Pyrex glass tubes was recrystallized from methyl acetate. The unit cell, as determined from a number of crystals, is orthorhombic, with  $a = 9.17$ ,  $b = 16.01$ ,  $c = 14.97$  Å; space group: either  $\text{Pbcm}$  or  $\text{Pbc}2_1$ . A formula weight of 574 is derived from the observed density of  $1.73 \pm 0.01$  g/cm<sup>3</sup> and the assumption of four formula units in the cell. Three-dimensional X-ray data were collected from a crystal of maximum dimension 0.15 mm, with the use of Mo K $\alpha$  radiation, by procedures previously described.<sup>3</sup> Comparison of the intensities of the  $hkl$  and  $hk\bar{l}$  reflections indicated that the space group is the polar noncentric one  $\text{Pbc}2_1$ , and this was confirmed by the positions of the Pt, Cl, and P atoms, as determined by Patterson and Fourier methods. By comparison of two least-squares refinements of the positions of the heavy atoms it proved possible to determine the direction of the polar axis at this stage, because of the anomalous scattering of the Pt atom. The positions of the ethyl carbon atoms could now be determined. The P atoms were seen to be *trans*, and the Pt-Cl direction was at right angles to the P-Pt-P axis. Structure factors calculated for this  $\text{PtCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  fragment led to a conventional  $R$  factor of 0.104. Inspection of the resulting difference Fourier map revealed no evidence of a  $\pi$ -bonded  $\text{C}_2\text{F}_4$  fragment. Two strong peaks close to the Pt of heights 4.5 and 6.5 e/Å<sup>3</sup> suggested a carbonyl group linearly bound to the Pt atom and completing a planar four-coordinate arrangement around the Pt. At a distance of at least 4 Å from the Pt atom was a group of four peaks in tetrahedral arrangement, heights 2-3 e/Å<sup>3</sup>, and there was a small peak at their center of gravity. These facts suggested refinement of a model corresponding to  $\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2^+\text{BF}_4^-$ , and this resulted in an  $R$  factor of 0.055. Refinement continues, but at this stage the bond lengths and angles in the cation are

Apart from the ethyl groups, the cation is essentially planar. The small deviations make the coordination tend toward a flattened tetrahedron rather than a square pyramid, and it is thus extremely unlikely that there is a hydrogen atom coordinated to the Pt atom. We conclude that recrystallization of the original sample gave a pure  $\text{BF}_4^-$  salt, and this is confirmed by comparisons of the infrared spectra of the recrystallized sample with both the original sample (containing both  $\text{BF}_4^-$  and  $\text{SiF}_6^-$ ) and a sample containing  $\text{SiF}_6^-$  only.

Further chemical and analytical studies have confirmed the chemical formulation suggested by the X-ray investigation. The original reactions were carried out in Pyrex glass tubes, which are now known to yield a mixture of  $\text{BF}_4^-$  and  $\text{SiF}_6^-$  anions, as noted above. On the basis of the analyses reported previously<sup>1</sup> (Found: Pt, 34.4; P, 10.7; F, 12.7), it is not possible to distinguish between the original postulate (Calcd for  $\text{PtHCl}(\text{C}_2\text{F}_4)(\text{P}(\text{C}_2\text{H}_5)_3)_2$ : Pt, 34.3; P, 10.9; F, 13.4) and the structure suggested by the X-ray study (Calcd for  $\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2^+\text{BF}_4^-$ : Pt, 33.5; P, 10.6; F, 13.1). However, treatment of the product with sodium tetraphenylboron led to a water-soluble fraction that contained  $\text{NaBF}_4$  and  $\text{Na}_2\text{SiF}_6$ . Conductivity studies<sup>1</sup> were consistent with a formulation as a 1:1 electrolyte. The infrared spectrum<sup>1</sup> confirms the presence of the *trans*- $\text{PtCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  fragment.<sup>4,5</sup> The absorption at  $2100\text{ cm}^{-1}$  may equally well be assigned as  $\nu(\text{Pt-H})$  or  $\nu(\text{C}\equiv\text{O})$ , but the high-resolution mass spectrum of the pyrolysis products of the  $\text{SiF}_6^-$  salt confirms the presence of carbon monoxide. The sharp absorptions at 1094, 1060, and  $881\text{ cm}^{-1}$ , which were previously assigned to C-F modes, are now known to be due to the anions. These spectra will be discussed in detail elsewhere, but we note that a splitting of the tetrafluoroborate  $\nu_4$  mode into two sharp absorptions ( $1094$  and  $1060\text{ cm}^{-1}$ ) has not been reported previously.

The final confirmation of the structure is the rational synthesis of the tetrafluoroborate salt. *trans*- $\text{PtHCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  reacts with carbon monoxide and aqueous tetrafluoroboric acid under pressure to yield *trans*-bis(triethylphosphine)chlorocarbonylplatinum(II) tetrafluoroborate,  $[\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2]\text{BF}_4$ . Anal. Calcd for  $\text{PtClC}_{12}\text{H}_{30}\text{P}_2\text{OBF}_4$ : C, 26.9; H, 5.2; B, 1.86; F, 13.1. Found: C, 27.4; H, 5.4; B, 2.0; F, 13.4.

When the original reaction between  $\text{PtHCl}(\text{P}(\text{C}_2\text{H}_5)_3)_2$  and  $\text{C}_2\text{F}_4$  is carried out in a silica tube, then the pure  $\text{SiF}_6^-$  salt can be isolated. That this is a  $\text{SiF}_6^-$  salt, rather than a  $\text{SiF}_6^{2-}$  salt, is strongly suggested both by the analytical data and the X-ray molecular weight. Anal. Calcd for  $\text{PtCl}(\text{CO})(\text{P}(\text{C}_2\text{H}_5)_3)_2\text{SiF}_6$ : C, 25.3; H, 4.9; Si, 4.5; F, 15.4; Pt, 31.6; P, 10.0; Cl, 5.7. Found: C, 24.9; H, 4.6; Si, 4.7; F, 15.2; Pt, 32.2; P, 9.9; Cl, 5.8. This salt is not isomorphous with the  $\text{BF}_4^-$  analog, although the unit cells are related. The

space group is  $Pbca$ , with  $a = 16.9$ ,  $b = 18.9$ ,  $c = 14.7$  Å. The formula weight from these data and the observed density is  $611 (\pm 1\%)$  (calcd for  $[PtCl(CO)(P(C_2H_5)_3)_2]SiF_6$ : 618; calcd for  $0.5[PtCl(CO)(P(C_2H_5)_3)_2]SiF_6$ : 566).

Although the previous conclusions<sup>1</sup> are now known to be incorrect, the reactions described above are remarkable in several ways. (a) The formation of a platinum carbonyl and  $BF_4^-$  under such mild conditions, presumably by interaction of  $C_2F_4$  with the glass surface in contact with the hydride, is remarkable. It can be related to, but is more extreme than, the ability of the isoelectronic Ir(I) and Rh(I) systems to abstract carbon monoxide from oxygen-containing organic solvents.<sup>2,3</sup> (b) The cation is isoelectronic with Vaska's compound<sup>4</sup> and may show similar properties. These are being investigated. (c) This is the first reported isolation of the  $SiF_6^-$  ion. Further detailed studies of this species are currently in progress.

## Opening the $B_{10}H_{12}^{2-}$ Cage to Produce $B_{10}H_{12}(Et_2S)_2$

Sir:

The preparations of  $B_{10}H_{12}(base)_2$  derivatives have been reported from reactions of decaborane with soft bases.<sup>1,2</sup> These have been converted further to the  $B_{10}H_{10}^{2-}$  structure by action of more or harder base.<sup>3</sup> We wish to report the synthesis of  $B_{10}H_{12}(Et_2S)_2$  from  $(NH_4)_2B_{10}H_{10}$ , which is the first time, to our knowledge, that the  $B_{10}H_{10}^{2-}$  cage has been opened to clearly reestablish the decaborane skeleton.

This reaction takes on further significance with the recent preparation in these laboratories of the  $B_{10}H_{10}^{2-}$  ion from simple borohydrides,<sup>4</sup>  $B_{10}H_{12}(Et_2S)_2$ , other  $B_{10}H_{12}(base)_2$  compounds,<sup>2,5</sup> and carboranes,<sup>6</sup> for example, can now be prepared from simple starting materials, by-passing decaborane as an intermediate.

The product is obtained from the reaction of  $(NH_4)_2B_{10}H_{10}$  and anhydrous HCl in ethyl sulfide (eq 1).

Reaction occurs readily at room temperature. A double salt,  $NH_4Cl \cdot (NH_4)_2B_{10}H_{10}$ , insoluble in ethyl sulfide, is produced as the by-product.  $B_{10}H_{12}(Et_2S)_2$  is recovered in approximately 92% yield based on the above equation from the filtrate by vacuum evaporation of the excess ethyl sulfide. Infrared, X-ray, and

nmr comparisons with authentic samples left no doubt as to its identity. The product was somewhat impure but gave elemental analyses approximating the desired compound.

**Anal.** Calcd for  $[(C_2H_5)_2S]_2B_{10}H_{12}$ : B, 36.0; C, 31.9; H, 10.6; S, 21.3. Found: B, 34.7; C, 29.6; H, 10.3; S, 20.3.

Work on recovery of the  $(NH_4)_2B_{10}H_{10}$  from the double salt by use of other solvents is in progress. With large excesses of HCl the reaction gives some free  $NH_4Cl$  and correspondingly higher quantities of  $B_{10}H_{12}(Et_2S)_2$ . Several samples have been allowed to react with propargyl bromide, and the expected bromomethyl-carborane derivative was obtained.<sup>6</sup>

Muetterties has reported obtaining a bridge-hydrogen structure from the  $B_{10}H_{10}^{2-}$  ion.<sup>6</sup> Dehydration of an aqueous solution of  $(H_2O)_2B_{10}H_{10}$  gave a white solid from which a material could be sublimed. The sublimate showed evidence for bridge hydrogens in its infrared pattern. The unknown had the approximate composition of  $B_{10}H_{12}OH_2$ . He concluded that the solid belonged to the  $B_{10}H_{12}(base)_2$  or  $B_{10}H_{12}^{2-}$  structural class. A referee has pointed out that the formation of  $B_{10}H_{12}$  from  $B_{10}H_{10}^{2-}$  plus acid involves opening  $B_{10}H_{10}$  cages. However, degradation with loss of boron also obviously occurred.<sup>7</sup>

Mechanistically the synthesis of  $B_{10}H_{12}(Et_2S)_2$  from  $(NH_4)_2B_{10}H_{10}$  can be pictured as just the reverse of the  $B_{10}H_{12}(base)_2$  conversion to  $B_{10}H_{10}^{2-}$  derivatives. Hawthorne suggests that this latter conversion occurs by the removal of protons from the bridge positions in the  $B_{10}H_{12}(base)_2$  structure, and that the resulting filled two-center orbitals undergo a nucleophilic displacement of the coordinated bases. In our reaction, protons which are presumably supplied *via* the ethylsulfonium ion,  $Et_2SH^+$ , probably attack in the apex region of the  $B_{10}H_{10}^{2-}$  cage. Nmr studies with deuterium chloride have established that hydrogen exchange occurs at the apex borons.<sup>8,9</sup> Single crystal X-ray

studies on  $\text{Cu}_2\text{B}_{10}\text{H}_{10}$  also show bonding with the  $\text{Cu}^+$  ions along apex-equatorial boron edges.<sup>10</sup>

Presumably cage-opening occurs *via* the formation of bridge hydrogens between apex and equatorial borons. Bond rupture and coordination of ethyl sulfide between the equatorial borons result with the ethyl sulfide coordinated borons now becoming the 6 and 9 positions of the resulting  $\text{B}_{10}\text{H}_{12}(\text{Et}_2\text{S})_2$  structure. A plausible mechanism is depicted in eq 2 (the numbering system used is that for decaborane and only the "mouth" borons are numbered). The rupture of the cage bonds may involve a multicenter reaction with the  $\text{Et}_2\text{SH}^+$  ion or simple displacement by some solvent ethyl sulfide.

## Enzymic Synthesis of $\beta$ -Amyrin from 2,3-Oxidosqualene

Sir:

Recent studies have demonstrated that lanosterol is synthesized in the mammalian liver from 2,3-oxidosqualene (1)<sup>1-3</sup> under the influence of an enzyme, 2,3-oxidosqualene-sterol cyclase, which can be obtained from liver microsomes in a partially purified water-soluble form.<sup>4</sup> The separation of the squalene-to-sterol conversion into discrete oxidation and cyclization steps suggests a similar possibility for the biosynthesis of pentacyclic triterpenes and, therefore, a powerful experimental approach for studying the details of the remarkable rearrangement processes which are supposed to lead from the lupanyl<sup>5</sup> system to the triterpenes of the oleanane ( $\beta$ -amyrin), ursane ( $\alpha$ -amyrin),<sup>6</sup> friedelane,<sup>7</sup> and other series. Since it has been shown that  $\beta$ -amyrin (2) is formed enzymically from squalene in a homogenate from germinating peas (*Pisum sativum*),<sup>8</sup> this system was selected for initial study. We report here an investigation which demon-

strates that 2,3-oxidosqualene is indeed a precursor of  $\beta$ -amyrin in *Pisum sativum* and that the cyclizing enzyme can be obtained in water-soluble form.

Anaerobic incubation for 24 hr at 37° of <sup>14</sup>C-labeled 2,3-oxidosqualene with a cell-free homogenate from *Pisum sativum* led to isolation of a product which showed upon thin layer chromatography on silica gel about 35% of the radioactivity in a band with an  $R_f$  equal to that of  $\beta$ -amyrin. That this material was in fact primarily  $\beta$ -amyrin was demonstrated by the following experiments. Recrystallization (ca. 2  $\mu$ -moles, 6000 counts/min) from ethanol-water with carrier  $\beta$ -amyrin (50 mg) led to a constant specific activity after the first crystallization (131, 106, 105, 104, 108 counts/min per mg). The combined fractions from this recrystallization experiment were acetylated with acetic anhydride in pyridine and chromatographed. The radioactivity was found in the zone characteristic of  $\beta$ -amyrin acetate using a thin layer of silica gel and 5% ethyl acetate-benzene for development. In addition, thin layer chromatography of acetylated biosynthetic material on a 20% silver nitrate-silica gel plate (3:2, chloroform-petroleum ether) showed the absence of labeled lanosterol and an  $R_f$  for the radioactive product identical with that of  $\beta$ -amyrin acetate. Vapor phase chromatography of acetylated labeled biosynthetic product using a glass column packed with 2% Epon 1001 on Diatoport S at 235° capable of separating  $\alpha$ - and  $\beta$ -amyrin acetates showed >95% of the radioactivity in the  $\beta$ -amyrin acetate peak.

The intermediacy of squalene 2,3-epoxide in the biogenesis of  $\beta$ -amyrin is further supported by an experiment using 2,3-iminosqualene, which has been shown to be a potent inhibitor of enzymic cyclization of 2,3-oxidosqualene to lanosterol.<sup>9</sup> Incubation of <sup>14</sup>C-labeled squalene in the presence of 2,3-iminosqualene with a cell-free homogenate from *Pisum sativum* capable of converting squalene to  $\beta$ -amyrin<sup>8</sup> led to isolation by chromatography of about 2% of the radioactivity in a band of  $R_f$  equal to that of 2,3-oxidosqualene (using silica gel with 3% ethyl acetate-benzene as solvent). Dilution of this material with carrier 2,3-oxidosqualene and treatment with perchloric acid in aqueous glyme led to a product which upon chromatographic separation (using silica gel with 20% ethyl acetate-benzene as solvent) manifested radioactivity almost totally in the band of  $R_f$  corresponding to 2,3-dihydroxylated squalene.<sup>2</sup>

The solubilization and partial purification of this 2,3-oxidosqualene- $\beta$ -amyrin cyclase from *Pisum sativum* has been effected by a procedure similar to that used in the purification of the 2,3-oxidosqualene-lanosterol cyclase from hog liver.<sup>4</sup> The cell-free homogenate<sup>8</sup> in pH 7.4 phosphate buffer (without added sucrose or glutathione) was treated at 0° with just sufficient sodium desoxycholate solution to effect clarification,

then an equivalent amount of calcium chloride solution was added to precipitate desoxycholate. supernatant solution was separated after centrifugation, and the enzyme was precipitated from 30% ammonium sulfate solution. The precipitate obtained after centrifugation (37,000g, 20 min) was taken up in phosphate buffer (pH 7.4) and centrifuged at 300g for 3 hr. The clear supernatant liquid removed by pipet and assayed for total protein activity in the anaerobic 2,3-oxidosqualene- $\beta$ -pin conversion. The particle-free solution had a specific activity in cyclization to  $\beta$ -amyrin (per mg of protein) approximately 12 times that of the original osomes.

Studies are continuing on the details of the enzymic cyclization of  $\beta$ -amyrin and other triterpenes.

**Acknowledgment.** We are pleased to acknowledge expert advice and assistance of Dr. P. D. G. Dean.

## Photochemical Rearrangement of $\alpha,\beta$ -Epoxy Ketones. Elaboration of the Mechanism

The photorearrangement of  $\alpha,\beta$ -epoxy ketones to  $\beta,\gamma$ -diketones (eq 1) is characterized by an unusual order of migrational aptitudes of various  $\beta$  groups (e.g.,  $I_2 \gg C_6H_5$ ).<sup>1,2</sup> Suggestions concerning the

Mechanism of this transformation have been advanced,<sup>1-4</sup> and our recent work in this area has disclosed certain features of the rearrangement that sup-

C. K. Johnson, B. Dominy, and W. Reusch, *J. Am. Chem. Soc.*, **85**, 194 (1963).

O. Jeger, K. Schaffner, and H. Wehrli, *Pure Appl. Chem.*, **9**, 364 (1964).

H. Wehrli, C. Lehmann, P. Keller, J. Bonet, K. Schaffner, and H. J. Eicher, *Helv. Chim. Acta*, **49**, 2218 (1966).

port the elaboration of these views presented in eq 2.

The formation of intermediate C from a singlet [ $S_1$ ] or triplet [ $T_1$ ] excited state is theoretically reasonable,<sup>5</sup> and the reactions leading to this species constitute the true "photochemistry" of these compounds. Inasmuch as the epoxy ketone rearrangements are not sensitive to the presence of oxygen or changes in the solvent, and since the addition of known triplet quenchers (piperylene and 2,5-dimethyl-2,4-hexadiene were used in concentrations ranging from 0.1 to 9.0 M) did not affect the rate or course of rearrangement (specifically shown for II, III, VII, and VIII), intermediate C appears to be formed predominantly from the initially produced ( $S_1$ ) state. Furthermore, acetophenone (0.5 M) did not function as a sensitizer for the rearrangement of II (0.3 M) in acetonitrile solution. The low quantum yield observed for some of these rearrangements (e.g., ca. 0.03 for the conversion of VII to 3-methylpentane-2,4-dione) may indicate poor efficiency for the [ $S_1$ ]  $\rightarrow$  C transformation, or an unfavorable competition between rearrangement and oxirane ring formation from C. A preliminary study involving reduction of [ $T_1$ ] by tri-*n*-butylstannane suggests that in the case of VII both factors are important.<sup>6</sup>

A recent report<sup>7</sup> concerning the thermal decomposition of  $\beta$ -methyl- $\beta$ -phenyl- $\beta$ -peroxypropylactone noted a fivefold preference for methyl migration *vs.* phenyl and suggested a 1,3-diradical intermediate similar to C. The implication that such a species can be generated by nonphotochemical pathways is supported by the isomerization and rearrangement of pulegone oxide diastereoisomers (VIII) at 200°. A rationalization of the abnormal migrational aptitudes found in rearrangements proceeding from intermediate C is achieved by assuming that the migrating group must have radical characteristics. This feature can be incorporated in a fragmentation (two-step) mechanism involving the caged radical pair D, or in a single step path having a transition state resembling D in certain respects.<sup>8</sup>

(5) H. E. Zimmerman, *Advan. Photochem.*, **1**, 183 (1963).

(6) This aspect of our investigations will be developed fully in a subsequent paper and should lead to a rough assignment of relative rates for the various steps in eq 2.

(7) F. D. Greene, W. Adam, and G. Knudsen, Jr., *J. Org. Chem.*, **31**, 2087 (1966).

(8) A detailed discussion of these rearrangements with particular emphasis on stereochemistry has been presented by the Zürich research group.<sup>3,4</sup> Their arguments are in favor of a synchronous mechanism.

This view of the reaction led us to anticipate an especially high migrational aptitude for benzyl and benzhydryl  $\beta$  substituents, and this has been confirmed by experiments with III and IV. Thus, irradiation<sup>9</sup> of a 0.025 *M* solution of IV in ether for 3.5 hr gave roughly 50% conversion to a 1:4 mixture of XI and XII.<sup>10</sup> The sole rearrangement product obtained from a similar irradiation of III proved to be X (*ca.* 20%), but this was accompanied by significant quantities of fragmentation products (*e.g.*, IX, dibenzyl and  $\alpha$ -benzylethyl ethyl ether). Since X was essentially unreactive under equivalent reaction conditions, the formation of the latter products suggests that intermediate C is in this case at least partly diverted to the radical pair D, and that the relatively stable benzyl radical escapes the solvent cage.

Other photochemical transformations recently established in our laboratory are: I to IX (*ca.* 40%) and XIII (*ca.* 4%); VI to XIV (*ca.* 40% by a technique involving continuous extraction of the product); and V to cyclopentane-1,3-dione and an unidentified base-soluble substance.

The rearrangements described in this communication together with previous findings<sup>1-4</sup> support the following rough order for the migrational aptitude of  $\beta$  substituents: benzhydryl and benzyl > hydrogen > methylene > methyl  $\gg$  phenyl. The position of hydrogen in this listing argues against a general fragmentation mechanism for the rearrangement, since hydrogen atoms are not normally produced in preference to alkyl radicals. Also, the formation of a strained four-membered ring (XIV) in the photolysis of VI<sup>11</sup> leads us to prefer a single step or synchronous route for rearrangement from C. If a radical pair (*i.e.*, D) was an intermediate in this rearrangement, the formation of a six-membered heterocyclic system or possibly fragmentation with loss of ethylene would seem to provide attractive alternate reaction modes. Products of this type were not found.

## Mass Spectrometric Studies on Aminocyclitol Antibiotics

Sir:

We wish to report preliminary results of a mass spectrometric investigation of the antibiotics paromomycin<sup>1</sup> and paromomycin II<sup>2</sup> (1a and 1b, respectively,

(1) (a) T. H. Haskell, J. C. French, and Q. R. Bartz, *J. Am. Chem. Soc.*, **81**, 3480 (1959); (b) T. H. Haskell and S. Hanessian, *J. Org. Chem.*, **28**, 2598 (1963).

TMS and Ac = H), members of the diaminocyclitol (deoxystreptamine) class of antibiotics.<sup>3-4</sup>

The above-mentioned antibiotics, together with the model compounds derived from them and from the neomycins by various degradative reactions,<sup>3-4</sup> were investigated in the form of their N-acetyl-O-trimethylsilyl derivatives. The use of the trimethylsilyl (TMS) blocking groups was found advantageous in the study of these molecules of low volatility. The N-acetyl and N-acetyl-3-d derivatives 1-6 (TMS = H) were prepared by selective N-acetylation of the respective free bases with acetic anhydride in methanol. The chromatographically homogeneous solids<sup>5</sup> (compounds 2, 4-6, TMS = H, were obtained crystalline) were then subjected to silylation with trimethylsilyl chloride and hexamethyldisilazane in dry pyridine.<sup>6</sup> The trimethylsilyl ethers 1-6 thus obtained were nonhygroscopic white solids which had the infrared and nmr spectral properties expected for N-acetyl-O-trimethylsilyl derivatives.

A minute molecular ion peak is present in the mass spectrum<sup>7</sup> of the N-acetyl-O-trimethylsilyl derivative of paromomycin II (1b). A peak of 2.5% intensity (relative to *m/e* 73, (CH<sub>3</sub>)<sub>3</sub>Si<sup>+</sup>) at *m/e* 1386 is characteristic of the loss of a methyl radical from a trimethylsilyl group.<sup>8</sup> Relatively intense peaks are also present at *m/e* 665 (4.0%), 420 (16.0%), and 389 (40.0%) from cleavages of glycosidic bonds as indicated in structure 1. Other fragments in the spectrum can be accounted for by further fragmentations of the molecular ion and of these fragment ions.

(3) J. D. Dutcher, *Advan. Carbohydrate Chem.*, **18**, 259 (1963).

(4) S. Hanessian and T. H. Haskell, "The Carbohydrates," Vol. 2, W. Pigman and D. Horton, Ed., Academic Press Inc., New York, N. Y., in press.

(5) Thin layer chromatography of the N-acetates was carried out on glass plates coated with Avirin (a product of American Viscose Corp., Marcus Hook, Pa.) and the compounds were detected by spraying lightly with a 1% solution of potassium permanganate in 1 *N* sulfuric acid or by exposure to iodine vapors.

(6) In a typical experiment, 0.1 g of N-acetyl derivative dissolved in 5 ml of dry pyridine was treated with 1 ml of trimethylsilyl chloride and 3 ml of hexamethyldisilazane at room temperature. After 1-2 hr the mixture was evaporated to dryness, the residue was suspended in benzene, and the soluble portion was evaporated to dryness and used as such.

(7) The mass spectra of compounds 2-6 were obtained from an Atlas CH4 mass spectrometer, using a vacuum-lock direct-inlet system. The authors wish to thank Dr. W. J. McMurray, Yale University School of Medicine, for obtaining the spectrum of compound 1b on an AE MS9 mass spectrometer.

(8) A. G. Sharkey, Jr., R. A. Friedel, and S. H. Langer, *Anal. Chem.*, **29**, 770 (1957).

Prominent peaks at  $m/e$  389 are also present in the mass spectra of model compounds 2 and 3 and shift to  $m/e$  395 in the spectrum of the  $d_6$  analog 4. The mass spectra of compounds 5 and 6 have peaks at  $m/e$  420, does the spectrum of 1. A few other important peaks are indicated in 2-6. All peak intensities are relative to  $m/e$  73,  $(CH_3)_3Si^+$ .

From these data, it is possible to recognize the sequential arrangement and gross structures of the units which the saccharides are comprised. Differences in stereochemistry and ring size most likely will not affect the indicated fragmentation paths. Compound 1 shows a preferential cleavage of glycosidic bonds, placing the charge on the carbon next to a ring oxygen where it can be stabilized by the nonbonding electrons on oxygen. Although all of the mass spectra in this study exhibited only minute molecular ion peaks (1-1% relative intensity), molecular weights can be readily determined from the more intense peaks 15 mass units lower.

Whereas the characterization of various amino and deoxy sugars derived from antibiotic substances has been successfully accomplished by mass spectrometric techniques,<sup>4,9,10</sup> the detailed analysis of intact anti-

biotics containing sugars is still relatively unexplored.<sup>4</sup> The few recorded examples belong to the class of macrolide (chalomycin,<sup>10</sup> pimaricin,<sup>11</sup> and aldagmycin<sup>12</sup>) and nucleoside (cordycepin,<sup>13</sup> puromycin<sup>14</sup>) antibiotics. The present investigation represents the first reported example of the application of mass spectrometry to the study of the gross structure of intact aminocyclitol antibiotics. It demonstrates the potential usefulness of this technique in providing crucial information concerning the structure of related compounds, from submilligram quantities of the appropriate derivatives and from minutes of instrument time. Experiments on the electron-impact-induced fragmentation of related aminocyclitol antibiotics are in progress.

## Metal-Ammonia Reduction of Nonconjugated Dienes and Enones<sup>1</sup>

Sir:

A consequence of a structurally imposed close proximity of two nonconjugated double bonds is that the energy of the lowest antibonding orbital of one is raised while that of the other is lowered. One of the several consequences of this which might be anticipated is the increased ability of the molecule to accept an electron in the relatively low energy antibonding orbital. It might be expected that the activation energy will be lowered and the equilibrium constant raised for the reversible process  $M + e^- \rightleftharpoons M^{\cdot-}$ . An example of this structural feature is norbornadiene (I). It appears to have no resonance energy in the ground state, and thus can in no sense be considered aromatic, but it has a significant 2-6 bonding contribution in the excited state.<sup>2</sup> A spectroscopic manifestation of this is its relatively long wavelength ultraviolet absorption ( $\lambda_{max}$  211 m $\mu$ ). We wish now to describe a chemical consequence of this perturbation, the reduction of such nonconjugated dienes and enones by metal-ammonia systems.

The reduction of I with sodium or lithium in carefully dried ammonia ( $-33^\circ$ ) afforded norbornene (II) in 98% yield.<sup>3</sup> No evidence for even traces of

(1) The authors are indebted to the National Science Foundation, Grant GP 6757, and to the University of Utah Research Fund for the support of this study.

(2) C. F. Wilcox, S. Winstein, and W. G. McMillan, *J. Am. Chem. Soc.*, **82**, 5450 (1960).

norbornane or nortricyclene in the product could be found.<sup>4</sup> To rule out the possibility that the difference in ease of reduction of I and II might be due to their difference in strain energy rather than to a double bond perturbation in I, a cyclobutene (III) was examined and found to be inert.

Norbornenone (IV,  $\lambda_{\max}$  301 m $\mu$  ( $\epsilon$  292)) was found to be reduced under these conditions to a mixture of diastereomeric pinacols (V).<sup>7</sup> Similar treatment of norbornanone ( $\lambda_{\max}$  287 m $\mu$  ( $\epsilon$  29)) gave only recovered starting material.

It is thus clear that the light absorption properties of a molecule, which reflect the difference between its ground- and excited-state energies, may be used qualitatively to predict the ease with which it can accept an electron in its lowest lying antibonding orbital. The energy of the excited molecule will obviously be different from that of the radical ion which is intermediate to the reduction product because the latter possesses one more electron.

This correlation predicts that a number of other types of compound might also be reducible by metal-ammonia systems. 1-*t*-Butyl-3,3-dimethylcyclopropene (VI,<sup>8</sup>  $\lambda_{\max}$  195 m $\mu$  ( $\epsilon$  4400)) was examined and found to be reduced extremely rapidly to the corresponding cyclopropane<sup>8</sup> (VII, 85%). Similarly, [2.2]paracyclophane (VIII)<sup>9</sup> underwent reduction to di-*p*-tolylethane (IX, 100%) under conditions employed with other sub-

strates.

An intriguing question posed in the facile reductions of I and IV is whether or not nonclassical radical ions

(3) "Isolated" double bonds are not reduced without an added proton source and even then only terminal double bonds are affected: H. Greenfield, R. A. Friedel, and M. Orchin, *J. Am. Chem. Soc.*, **76**, 1258 (1954).

(4) The reduction of I to norbornane and nortricyclene with lithium in ethylamine (Benkeser conditions<sup>5</sup>) has been reported.<sup>6</sup> It should be noted that this technique is effective in reducing virtually all isolated double bonds.

(6) J. G. Traynham, *ibid.*, **25**, 833 (1960).

(7) The mixture (60%, mp 80–83°) was not separated but gave satisfactory nmr, infrared, and mass spectral data and analyzed correctly for  $C_{11}H_{16}O_2$ . Periodic acid cleaved it to norbornenone (83%).

(9) D. J. Cram, N. L. Allinger, and H. Steinberg, *J. Am. Chem. Soc.*, **76**, 6132 (1954), describe the spectral properties of [2.2]paracyclophane. We are indebted to Professor Cram for a generous sample of this material.

are involved. Particularly in the reduction of IV there can be little doubt that the intermediate X is extremely long-lived relative to typical nonconjugated radical ions. Repeated attempts<sup>10</sup> to obtain evidence for nonclassical behavior in the norbornenyl radical have failed, and it appears there is none. The radical ion in question here is electronically quite different, however, and its pronounced stability (long life) is suggestive of a nonclassical structure. An alternate

rationale based on steady-state concentration differences of radical ions cannot be dismissed ( $M + e^- \rightleftharpoons M^{\cdot-}$ ,  $k_1$  being very different but  $k_{-1}$  being similar for norbornanone and norbornenone), but it is considered unlikely.

## A Symmetrical Alternative to the Tetrahydropyranyl Protecting Group

Sir:

An obvious inherent disadvantage in the use of the tetrahydropyranyl group for the protection of optically active alcohols is that it leads to the introduction of an additional asymmetric carbon center (or centers), and thereby to mixtures of diastereoisomers being obtained.<sup>1</sup>

In connection with our work on oligoribonucleotide synthesis,<sup>2</sup> we undertook the preparation of a series of 2'-O-tetrahydropyranyl ribonucleosides (I) and obtained mixtures of diastereoisomers.<sup>3</sup> Although the latter could be separated and obtained crystalline,<sup>4</sup> the yield of pure isomer did not normally exceed 50%. However, after an unsuccessful attempt to isolate a pure crystalline 2',5'-bis(tetrahydropyranyl) ribonucleoside derivative, the search for an alternative, symmetrical acid-labile protecting group become more urgent. Unlike other workers engaged in oligoribonucleotide synthesis,<sup>5</sup> we have concluded<sup>6</sup> that the tetrahydropy-

(1) C. W. Greenhalgh, H. B. Henbest, and E. R. H. Jones, *J. Chem. Soc.*, 1190 (1951); A. N. de Belder, P. J. Garegg, B. Lindberg, G. Petropavlovskii, and O. Theander, *Acta Chem. Scand.*, **16**, 623 (1962).

(2) B. E. Griffin and C. B. Reese, *Tetrahedron Letters*, 2925 (1964).

(3) B. E. Griffin, M. Jarman, and C. B. Reese, *Tetrahedron*, in press.

(4) As it is intended that the synthetic oligomers should contain only 3'→5' internucleotidic linkages, it is a reasonable precaution to use only pure crystalline 2'-protected ribonucleoside derivatives (e.g., I) as intermediates.

(5) D. H. Rammiller and H. G. Khorana, *J. Am. Chem. Soc.*, **84**, 3112 (1962); J. Smrt and S. Chládek, *Collection Czech. Chem. Commun.*

ranyl acetal system has approximately optimal hydrolysis properties for an acid-labile protecting group: it may be removed under very mild conditions,<sup>6</sup> but is stable enough to allow protected oligomers to be purified.

Thus a satisfactory solution to this problem would be to find a symmetrical ketal system which underwent hydrolysis, in aqueous acid, at approximately the same rate as the tetrahydropyranyl group.<sup>6</sup> However, the best approach to such a solution was not immediately apparent as it had been reported<sup>8</sup> that simple ketals were over  $10^3$  times more labile than the corresponding acetals.<sup>9</sup>

Chart I

The 2'-acetone and cyclohexanone ketals of uridine (IIIa and IIIb) were prepared<sup>10</sup> from 3',5'-di-O-acetyluridine<sup>11</sup> (II) and the appropriate enol ethers (2-methoxypropene<sup>12</sup> and 1-methoxycyclohexene,<sup>13</sup> respectively) by the procedure indicated in Chart I. The half-times of hydrolysis of these derivatives at 20° and pH 4 are given in Table I. As the rate of ketal

Table I. Half-times ( $t_{1/2}$ ) of Hydrolysis of Uridine 2'-Ketals (III)<sup>a</sup> in 0.1 M Aqueous Sodium Citrate (pH 4.0) at 20°

Compd	Yield, % <sup>b</sup>	Mp, °C	$t_{1/2}$ , min
IIIa	42	185 dec	4 <sup>c</sup>
IIIb	30	149–151	10

<sup>a</sup> 0.02 M solutions of nucleoside derivatives were used. <sup>b</sup> Represents over-all yield based on II. <sup>c</sup>  $t_{1/2}$  for the corresponding 5'-protected uridine derivative was reported to be 1 min in 0.1 M acetate buffer (pH 4.7) at 25° (A. Hampton, *J. Am. Chem. Soc.*, **87**, 4654 (1965)).

hydrolysis<sup>8</sup> is proportional to  $[H^+]$ ,  $t_{1/2}$  for IIIa may be calculated to be 0.04 min at 20° and pH 2. As anticipated, this is less than  $10^{-3}t_{1/2}$  for 2'-O-tetrahydropyranyluridine<sup>6</sup> under the same conditions. Surprisingly,<sup>14</sup> the cyclohexanone ketal IIIb is only 2.5 times more stable than IIIa.

31, 2978 (1966); F. Cramer, H.-J. Rhaese, S. Rittner, and K.-H. Scheit, *Ann.*, **683**, 199 (1965).

(6) At pH 2 (in 0.01 N hydrochloric acid solution) and 20°, the half-time ( $t_{1/2}$ ) of hydrolysis of 2'-O-tetrahydropyranyluridine (I, B = uracil-1) is 80 min. Thus the tetrahydropyranyl group may be removed from a protected oligomer with a negligible amount of concomitant degradation and isomerization.<sup>7</sup>

(7) D. M. Brown, D. I. Magrath, A. H. Neilson, and A. R. Todd, *Nature*, **177**, 1124 (1956).

(8) M. M. Kreevoy and R. W. Taft, Jr., *J. Am. Chem. Soc.*, **77**, 3146, 5590 (1955).

(9) The latter are, in turn,  $>10^3$  times as labile as the corresponding formaldehyde acetals. Thus<sup>9</sup> the relative rates of hydrolysis of  $CH_2(OEt)_2$ ,  $MeCH(OEt)_2$ , and  $Me_2C(OEt)_2$  at 25° in dioxane-water are  $1:6 \times 10^3:1.8 \times 10^7$ .

(10) Satisfactory analytical data were obtained for all new compounds described.

(11) H. P. M. Fromageot, B. E. Griffin, C. B. Reese, and J. E. Sulton, *Tetrahedron*, **23**, 2315 (1967).

(12) L. Claisen, *Chem. Ber.*, **31**, 1019 (1898).

(13) D. G. Lindsay and C. B. Reese, *Tetrahedron*, **21**, 1673 (1965).

(14) H. C. Brown, R. S. Fletcher, and R. B. Johannessen, *J. Am. Chem. Soc.*, **73**, 212 (1951).

It had been shown<sup>8</sup> that acetal and ketal systems could be stabilized to acidic hydrolysis by the introduction of electron-withdrawing groups. The idea that the inductive effect of a  $\beta$ -oxygen atom, if the latter were constrained in a ring system, might be sufficient for the present purpose was suggested by the fact that the  $pK_a$  of morpholine (8.70) was 2.52 units less than that of piperidine.<sup>15</sup> This indicates that a  $\beta$ -oxygen atom can destabilize a substituted ammonium ion by a factor of *ca.* 330. As the rate of ketal hydrolysis depends on the stability of the intermediate carbonium ion,<sup>8</sup> an estimate of  $t_{1/2} = 33$  min at pH 2 and 20° can be made for the hydrolysis of the uridine 2'-ketal of tetrahydro-4-pyrone (V) if the  $\beta$ -oxygen atom is assumed to exert an equivalent destabilizing effect on a carbonium ion.<sup>16</sup>

VIa, R = H  
b, R = Ac

Reaction between 3',5'-di-O-acetyluridine<sup>11</sup> (II) and excess of 4-methoxy-5,6-dihydro-2H-pyran<sup>17</sup> (IV) in the presence of toluene-*p*-sulfonic acid followed by treatment with methanolic ammonia gave the required uridine 2'-ketal (V) as a crystalline solid, in 61% yield. As indicated in Table II, its acid lability ( $t_{1/2} = 24$  min at pH 2 and 20°) is remarkably close to the above estimate and is *ca.* three times as great as that of 2'-O-tetrahydropyranyluridine.<sup>6</sup> In the same way the corresponding thymidine 5'-ketal, a useful intermediate in oligodeoxyribonucleotide synthesis, was prepared from 3'-O-acetylthymidine in 85% over-all yield. It is noteworthy that the 5'-ketal is more acid labile than the 2'-ketal system (see Table II).

Reaction between 3'-O-acetyluridine<sup>11</sup> and the enol ether IV under the usual conditions gave the diprotected derivative VIb (R = uracil-1), isolated as a crystalline solid in over 50% yield. Although the product VIa (B = uracil-1), obtained by treating the latter with methanolic ammonia, has not yet been in-

(15) A. Albert and E. P. Serjeant, "Ionization Constants of Acids and Bases," Methuen & Co. Ltd., London, 1962, p 141.

(16) The tetrahydro-4-pyrone ketal V is assumed to be 330 times more resistant to acidic hydrolysis than the cyclohexanone ketal IIIb. The latter would be expected to have  $t_{1/2} = 0.1$  min at pH 2 and 20° (see Table I).

(17) When 4,4-dimethoxytetrahydropyran [bp 64–66° (15 mm)], obtained from tetrahydro-4-pyrone<sup>18</sup> in 94% yield, was distilled with mesitylenesulfonic acid (0.1% by weight), 4-methoxy-5,6-dihydro-2H-pyran (IV) [bp 156–157° (760 mm)] was obtained in over 75% yield. In reactions with nucleoside derivatives, *ca.* 8 molecular equiv of IV was used per hydroxyl function to be protected.

(18) S. Olsen and R. Bredoch, *Chem. Ber.*, **91**, 1589 (1958).

Table II. Tetrahydro-4-pyrone Ketals of Nucleosides

Nucleoside derivative	Mp, °C	Yield, % <sup>a</sup>	[α] <sub>D</sub> <sup>20</sup> , deg <sup>b</sup>	t <sub>1/2</sub> , min <sup>c</sup>

Thymidine 5'-ketal	169-171	85	+9.7	10.5
Uridine 2',5'-bisketal <sup>d</sup> (VIa, B = uracil-1)		51	+2.4	9.5 <sup>e</sup>
Adenosine 2',5'-bisketal (VIa, B = adenine-9)	183-184	52	-50	

<sup>a</sup> Based on two steps from 3'-O-acetyl or 3',5'-di-O-acetyl nucleoside. <sup>b</sup> At suitable concentrations, in ethanol solution. <sup>c</sup> At 20° in 0.01 N hydrochloric acid. <sup>d</sup> Obtained as a glass in quantitative yield from its crystalline 3'-O-acetate (VIb, B = uracil-1; mp 102-104°). <sup>e</sup> For conversion of starting material into a mixture of 2'- and 5'-monoketals.

duced to crystallize, the corresponding adenosine derivative VIa (B = adenine-9) has been isolated as a crystalline solid in 52 % over-all yield (see Table II).

Thus the tetrahydro-4-pyrone ketal system (methoxytetrahydropyranyl group) appears to be most suitable for the protection of alcoholic hydroxyl functions in oligoribonucleotide synthesis; it has the required acid lability, and its use leads to satisfactory yields of pure crystalline mono- and diprotected ribonucleoside derivatives. This symmetrical ketal system should prove to be a useful alternative to the tetrahydropyranyl protecting group in other branches of natural product chemistry.

## Mechanism of the Oxidation of Monohydric Alcohols with Lead Tetraacetate. Rearrangement in the Triarylmethanol Series

Sir:

In recent years the ability of lead tetraacetate to oxidize monohydric alcohols has been exploited extensively from the synthetic standpoint.<sup>1</sup> Many of the products formed in this versatile reaction can be accounted for in terms of a mechanism involving the initial production of alkoxy radicals.<sup>1,2</sup> However, other mechanisms have been considered,<sup>1-3</sup> and the

evidence for radicals as prime intermediates has remained suggestive rather than conclusive. The present communication reports the discovery of a novel lead tetraacetate induced rearrangement whose investigation has yielded definitive information regarding the mechanism of the alcohol oxidation reaction.

Triphenylmethanol (1a) reacts with lead tetraacetate<sup>4</sup> in benzene, benzene-pyridine, or acetonitrile to form hemiketal ester 2a in yields ranging up to 91%.<sup>5</sup> Although the hydrolytic instability of 2a has prevented

its isolation, its presence has been conclusively established by infrared, nmr, and chemical ionization mass spectral measurements<sup>6</sup> on crude reaction products, and by the formation of benzophenone, dimethoxydiphenylmethane, methoxyphenoxydiphenylmethane, acetic acid, and phenol upon saponification of crude 2a with potassium hydroxide in aqueous methanol.

Reactions of lead tetraacetate with 1b or 1c gave mixtures of hemiketal acetates 2b,c or 2d,e.<sup>5</sup> These mixtures were hydrolyzed, and relative migratory aptitudes for the substituted aryl groups were then calculated from the amounts of ketones and ketals thus obtained. In the case of 1b, the lead tetraacetate reactions were run in benzene, benzene-pyridine, benzene-pyridine containing a soluble copper catalyst, acetonitrile, and acetonitrile containing cupric acetate.<sup>4</sup> Despite the wide variations in conditions and their attendant effects upon reaction rate, all of these experiments gave the same statistically corrected ratio for *p*-nitrophenyl:phenyl migration (within experimental error). Its value was  $4.4 \pm 0.3$ , a result which demands the operation of a homolytic mechanism.<sup>7</sup> Competitive occurrence of an ionic mechanism is ruled out by the insensitivity of the ratio to solvent polarity and the presence of copper salts or pyridine.<sup>8</sup> A concerted homolytic mechanism (see below) seems unlikely, since it would require a dependence of the ratio upon the nature of the leaving group.<sup>9</sup> Therefore, in this case it appears that the alkoxy radical corresponding to 1b is the sole rearranging species.<sup>10</sup>

ever, the alkoxy radical mechanism is not the one through which the rearrangement can proceed.

In the case of 1c, the occurrence of *two* mechanisms is clearly shown by the marked influence of reaction conditions upon the *p*-methoxyphenyl:phenyl migration (Table I). The low ratios obtained with lead and copper salts are believed to reflect the dominant operation of the alkoxy radical mechanism,<sup>8,11</sup> while the high values obtained in acetone and the experiments using nitrobenzene are consistent with the preferential decomposition of a first-order Pb(IV) alcoholate *via* a concerted, quasiionic<sup>11</sup> process (either heterolytic or homolytic) involving aryl migration. Our results suggest that the quasiionic mechanism is likely to be observed only in cases where migrating groups bearing strongly electron-donating substituents are near the hydroxyl function.

The use of nitrobenzene caused no marked increases in reaction rate or hemiketal ester yields, did not cause the formation of new products, failed to reduce the overall al balance (based on 1c), and was not used in sufficient concentration to affect medium polarity. Apparently, its effect upon the *p*-methoxyphenyl:phenyl migration is apparently due to selective inhibition<sup>6a</sup> of the radical chain process rather than to selective action of the quasiionic mode. A scheme which accounts for the available facts relating to the radical mechanism is shown below.<sup>12</sup>

*p*-Methoxyphenyl:phenyl migratory ratios for alkoxy radical mechanisms have apparently not been reported previously. However, groups are known to show comparable reactivities in the homophenyl rearrangement [C. Rüchardt and R. Hecht, *Tetrahedron* 1961 (1962)]. Ionic decompositions of *p*-methoxytriphenylhydroperoxide<sup>7b</sup> and the corresponding perbenzoate (I. J. Ph.D. Thesis, University of Kansas, 1960) give preferential *xyphenyl* migration.

A similar scheme which does not involve Pb(III) species is also

## Termination

In view of the foregoing observations, the occurrence of radical chain mechanisms in the oxidation of other types of monohydric alcohols with lead tetraacetate seems highly probable.

**Acknowledgment.** The author is indebted to Mr. H. J. Tarski for valuable technical assistance and to Dr. F. H. Field for the chemical ionization mass spectra.

New Syntheses of Alloxazines<sup>1</sup>

Sir:

Alloxazines and isalloxazines<sup>2</sup> are customarily prepared by condensation of (a) an *o*-phenylenediamine with alloxan,<sup>3</sup> (b) a 4,5-diaminopyrimidine with an *o*-benzoquinone,<sup>4</sup> (c) an *o*-aminoazobenzene with a barbituric acid,<sup>5</sup> (d) a 5-nitrosopyrimidine with an aromatic amine<sup>6</sup> or an *o*-phenylenediamine,<sup>7</sup> or (e) by nitrosation of a 6-arylaminoaracil.<sup>8</sup> We wish to report three new synthetic approaches to alloxazines which not only are applicable, in principle, to the preparation of other condensed pyrazine heterocycles, but which offer further versatility in the synthesis of alloxazines with different origins for N<sub>8</sub> and N<sub>10</sub>.

**Method A.** Recent studies on the deoxygenation of aromatic nitro compounds by triethyl phosphite<sup>9</sup> support the intermediacy of nitrene intermediates. Capture of these nitrenes by intramolecular insertion has been utilized for the preparation of a number of heterocyclic systems (carbazoles,<sup>10</sup> benzotriazoles,<sup>10</sup> indazoles,<sup>10</sup> phenothiazines,<sup>11</sup> anthranils,<sup>11</sup> indoles,<sup>10,12</sup> pyrrolo[3,2-*d*]pyrimidines<sup>13</sup>). We report the first application of this procedure to the synthesis of a condensed pyrazine system. Thus, refluxing 1,3-di-

methyl-5-nitro-6-anilinouracil (1), mp 200.1°, in excess triethyl phosphite under N<sub>2</sub> for 2 hr, removal of volatiles by partial evaporation under a vigorous stream of N<sub>2</sub>, and dilution with ethanol gave 1,3-dimethylalloxazine (3),<sup>14</sup> mp 243.3° (30%). It is of considerable interest that the major product of this reaction was 1,3-dimethyl-6-anilinouracil, mp 187.7°. To our knowledge, this is the first example of denitration in the pyrimidine series. Similarly, heating 1,3-dimethyl-5-nitro-6-(3,4-xylidino)uracil (2), mp 212–214°, in triethyl phosphite for 7.5 hr gave a mixture of 1,3,7,8-tetramethylalloxazine (4), mp 253–254°<sup>15</sup> (14%), and 1,3,6,7-tetramethylalloxazine (5), mp 273.3°, along with the product of denitration, 1,3-dimethyl-6-(3,4-xylidino)uracil, mp 233.6°.

**Method B.** 1,3-Dimethylalloxazine (3) was prepared in 61% yield by portionwise addition of 1.5 moles of lead tetraacetate to a refluxing ether suspension of 1,3-dimethyl-5-amino-6-anilinouracil (6), mp 160.3°, followed by filtration and washing with water. The same conversion could be effected in lower yield (48%) by heating an intimate mixture of 6 with lead dioxide at 220°.

**Method C.** Refluxing 1 equiv of 1,3-dimethyl-6-aminouracil (7) with 2 equiv of nitrosobenzene, *p*-chloronitrosobenzene, or *p*-nitrosotoluene in acetic anhydride for 15 min, followed by dilution with water, gave 1,3-dimethylalloxazine (3), 52%, 1,3-dimethyl-8-

(14) Satisfactory microanalytical and spectral data were obtained for all compounds reported.

## Correlation between the Photochemistry and the Mass Spectra of Pyruvic Acid and Isopropyl Pyruvate<sup>1,2</sup>

Sir:

We wish to report an interesting correlation between the mass spectral behavior and photochemistry of both pyruvic acid and its isopropyl ester. Although processes which are general in photolyses have long been known to have analogs in mass spectral fragmentations,<sup>1</sup> the cases reported here are examples of unusual behavior of two molecular ions which are paralleled by unusual behavior of two corresponding *n*, $\pi^*$  excited states. Such an observation is significant in that it provides evidence for the validity of attempts to interrelate the mass spectrometry and photochemistry of organic molecules.

Photolysis of pyruvic acid in the vapor phase<sup>3</sup> and in aqueous solution<sup>4</sup> yields acetaldehyde and CO<sub>2</sub>, and acetoin, respectively. The reaction has been proposed to involve an *n*, $\pi^*$  state which forms an uncommon five-membered transition state.<sup>5</sup> The latter collapses to CO<sub>2</sub> and methylhydroxycarbene which then rearranges to acetaldehyde. From Table I it can be seen that the analogous process occurs in the mass

P. A. Leermakers, P. C. Warren, and G. F. Vesley, *J. Am. Chem. Soc.*, **86**, 1768 (1964).  
Also there are no  $C_5H_6O_2^+$  ions which might be expected by analogy to the double hydrogen rearrangement common in esters.<sup>9</sup>

$C_4H_7O_2^+$ ,  $C_4H_6DO_2^+$ , and  $C_4H_5O^+$  serve as evidence of the importance of cleavage of the CO-CO bond (reaction 2).

Further studies of these and other systems are being pursued in order to understand better the chemistry of molecules ionized by electron impact and to determine how the structures and reactivities of electronically excited states and molecular ions may be correlated.

## On the Mechanism of Lanosterol Biosynthesis from Squalene 2,3-Oxide

Sir:

In connection with our continuing program concerned with the organic and biological chemistry of terpenoid terminal epoxides,<sup>1</sup> we wish now to present new findings and considerations which further delineate the role of squalene 2,3-oxide in the biosynthesis of lanosterol and therefore other members of the sterol class.

Although recent experiments in these laboratories<sup>2</sup> and elsewhere<sup>3</sup> indicated that  $^{14}C$ -labeled squalene 2,3-oxide<sup>1a</sup> can be biosynthesized and also act as a natural triterpene source of lanosterol and cholesterol, the fate of oxygen in the original epoxide moiety was left unsettled. The following experiments elucidate this matter. Squalene 2,3-oxide- $^3H$ ,  $^{18}O$  (4150 dpm/ $\mu g$ , 30%  $^{18}O$  by mass spectral comparison<sup>4</sup> of normal and  $^{18}O$ -labeled oxides) was prepared from squalene- $^3H$  (4350 dpm/ $\mu g$ ) by the action of N-bromo-succinimide<sup>1a</sup> in 3:1 THF-water (30%  $^{18}O$ -labeled) and was incubated anaerobically with washed microsomes of rat liver in 0.08 M potassium phosphate buffer, pH 7.4. The sterol fraction was isolated, and lanosterol ( $R_f$ , 0.43; 200,000 dpm) was separated by tlc on silica gel in 15% ethyl acetate-hexane. Purification by glpc of the trimethyl silyl ether on a 6 ft  $\times$  0.25 in. column of 5% Carbowax on Chromosorb W at 235° gave lanosterol trimethylsilyl ether (retention time relative to cholestane = 3.7) which on mass spectral analysis was found to contain 29% excess  $^{18}O$ . The retention of the original epoxy oxygen as the 3 $\beta$ -hydroxyl group of lanosterol supports the mechanism proposed earlier<sup>2,3</sup> for the proton-initiated enzymic cyclization of squalene 2,3-oxide to lanosterol. Moreover, our inability to demonstrate any cofactor requirements for the microsomal enzyme system is also consistent with the proposed mechanism.

(1) Initial publications in this series: (a) E. E. van Tamelen and T. J. Curphey, *Tetrahedron Letters*, 121 (1962); (b) E. E. van Tamelen, A. Storni, E. J. Hessler, and M. Schwartz, *J. Am. Chem. Soc.*, **85**, 3295 (1963).

(2) E. E. van Tamelen, J. D. Willett, R. B. Clayton, and K. E. Lord, *ibid.*, **88**, 4752 (1966).

(3) E. J. Corey and W. E. Russey, *ibid.*, **88**, 4750 (1966), have also recorded the biochemical conversion of squalene 2,3-oxide<sup>1a</sup> to sterols.

(4) K. Biemann, "Mass Spectrometry, Organic Chemical Applications," McGraw-Hill Book Co., Inc., New York, N. Y., 1962, pp 204-205.

In an effort to locate additional intermediates in the over-all squalene  $\rightarrow$  lanosterol conversion, other oxidation products of squalene were prepared and tested for incorporation. Through the use of techniques previously described,<sup>2</sup> labeled lanosterol was not detected after incubation of <sup>3</sup>H-labeled 2,3-dihydrosqualene-2,3-diol,<sup>5</sup> 2,3-dihydrosqualen-2-ol,<sup>6</sup> and squalene 2,3:22,23-dioxide<sup>1a</sup> with rat liver homogenate.

Previous chemical investigations of the synthesis and cyclization of terpenoid terminal epoxides have revealed striking similarities between nonenzymic behavior on the one hand and squalene-squalene oxide biochemistry on the other. First, the unique, highly selective terminal oxidation of squalene by NBS in aqueous-organic solution<sup>1a</sup> simulates the observed biological conversion of squalene to its 2,3-oxide.<sup>2,3</sup> Second, laboratory cyclization of sesqui-<sup>1b,7</sup> or diterpenoid<sup>8</sup> terminal epoxides (I) to 3-hydroxylated polycyclic systems (II) with either "natural" (a-b-c-d *cis,trans,trans*) or biosynthetically attractive<sup>9</sup> (a-b-c-d *cis,trans,cis*) stereochemistry closely resembles genera-

tion of the AB moiety of lanosterol and other polycyclic terpenes in living systems. Third, just as most intermediary mono-, bi-, or tricyclic olefins which would have to reprotonate before enzymic conversion to lanosterol are ruled out,<sup>10,11</sup> monocyclohexenic products resulting from nonenzymic partial cyclization of sesquiterpenoid terminal epoxides are not intermediates in the conversion of these acyclic epoxides to 3-hydroxylated bicyclic (II) materials.<sup>7,12</sup>

The above parallelism encourages us to attempt further extrapolation from the purely organic to the biochemical area. Thus, it is noted that in epoxide cyclizations of type I  $\rightarrow$  II, the  $\pi$ -electron orbitals of the closest olefinic bond are ideally directed in space for interaction with a developing empty orbital at the more highly substituted position of the epoxide unit,

(11) Previous data<sup>10</sup> do not exclude (i) since the proton lost in its

formation does not appear in any case in the final product, lanosterol.

(12) E. E. van Tamelen and E. J. Hessler, *Chem. Commun.*, 411 (1966).

implying that a combined oxide ring opening-carbo-cyclization process having SN2 character is easily possible and may well be anchimerically assisted. By superimposition of this epoxide cyclization picture on the now familiar portrayal of lanosterol (or presterol) formation from acyclic precursor,<sup>9,13</sup> mechanism III ( $\rightarrow \rightarrow$  VI) emerges. Present biochemical evidence does not distinguish between a concerted cyclization and a stepwise annelation process involving conformationally rigid carbonium ions or the corresponding tertiary alcohols (or derivatives thereof, such as phosphates). An alternative possibility which is also completely consistent with the body of biochemical tracer

experiments<sup>14</sup> features cyclization of squalene oxide to a tricyclic intermediate with a five-membered C ring, followed by hydrogen migration to IV, this over-all process being identical (but not necessarily with regard to stereochemistry) with that observed during the nonenzymic cyclization of squalene oxide.<sup>15</sup> Completion of the biosynthetic scheme involves cyclization to a spiro system (IV  $\rightarrow$  V) coupled with and succeeded by concerted hydrogen, methyl, and alkyl migration (V  $\rightarrow$  VI).<sup>16</sup> Presentation of the above considerations should in no way be taken to indicate mechanistic preferences by us at the present time.

### Solvolytic Reactivity of 1-Chlorobicyclo[1.1.1]pentane<sup>1</sup>

Sir:

It is generally observed that the reactivity of bridgehead halides decreases markedly as the size of the bridging rings decreases.<sup>2</sup> Thus, the reactivities of several bridgehead halides are

The changes in reactivity have been attributed to the difficulty in creating a planar carbonium ion at the bridgehead position, increasing deviation from planarity increasing the energy of the ion formed.<sup>3</sup>

A significant exception to the trend is found with 1-bromobicyclo[2.1.1]hexane, which reacts  $10^7$  more rapidly than 1-bromonorbornane.<sup>4</sup> We now wish to report that the next lower homolog, 1-chlorobicyclo[1.1.1]pentane, is three times more reactive than *t*-butyl chloride and about  $10^{14}$  more reactive than 1-chloronorbornane.

1-Chlorobicyclo[1.1.1]pentane was prepared by the photochlorination of bicyclo[1.1.1]pentane.<sup>5</sup> The products were the 1-chloro derivative (25%), the 2-chloro derivative (7%), the 1,3-dichloride (5%), the 2,2-dichloride (33%), the 1,2-dichloride (5%), and 3-methylenecyclobutyl chloride (25%). The predominant attack by chlorine atoms at the bridgehead position, as contrasted to norbornane,<sup>6</sup> appears to result from the

(5) We have previously reported the isolation and characterization of the 1- and 2-chlorides via the photochemical reaction of the hydrocarbon with *t*-butyl hypochlorite: K. B. Wiberg and D. S. Connor, *ibid.*, **88**, 4437 (1966).

(6) E. C. Kooyman and G. C. Vegter, *Tetrahedron*, **4**, 382 (1958).

marked deactivation of the methylene positions as compared with cyclohexane.<sup>7</sup>

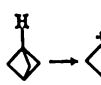

The 1-chloro derivative underwent solvolysis in 80% ethanol with rate constants of  $3.03 \times 10^{-5} \text{ sec}^{-1}$  at 25° and  $6.26 \times 10^{-4} \text{ sec}^{-1}$  at 50°, giving  $\Delta H^\ddagger = 12.0 \text{ kcal/mole}$  and  $\Delta S^\ddagger = +4 \text{ eu}$ . The products were 3-methylenecyclobutanol and its ethyl ether. Under the same conditions, the rate constant for *t*-butyl chloride was found to be  $9.67 \times 10^{-6} \text{ sec}^{-1}$  at 25°.<sup>8</sup>

The high reactivity of the chloride may be attributed to the driving force for ring fragmentation, relieving considerable strain. However, the same is true with the bicyclo[2.1.1]hexane derivative which is  $10^7$  less reactive. An alternative explanation is derived from our examination of the energy of the cyclobutyl cation<sup>11</sup> using the CNDO method.<sup>12</sup> Here, we assume that the activated complex for the solvolysis still retains significant bonding to the leaving group, thus making appropriate a tetrahedral geometry for the reacting center. The previous calculations suggested that an equatorial leaving group would be strongly preferred over an axial leaving group because of the possibility of a cross-ring interaction with the former.

This is in good accord with the experimental observations.<sup>9,10</sup> An extension to the bicyclo[1.1.1]pentane case would seem favorable because of the collinear geometry of the bridgehead bonds and the extremely short cross-ring distance (1.8–1.9 Å). The calculated energies for conversion of the corresponding hydrocarbon to the cation, a hydrogen atom, and an electron are indicated in Table I. It can be seen that the energy

Table I. Energy of Formation of Some Cations

Reaction	$\Delta E$ , au
$\text{CH}_4 \longrightarrow \text{CH}_3^+ + \text{H} \cdot + e^-$	0.9190
$\text{C}_2\text{H}_6 \longrightarrow \text{C}_2\text{H}_5^+ + \text{H} \cdot + e^-$	0.8230
$\text{C}_3\text{H}_8 \longrightarrow i\text{-C}_3\text{H}_7^+ + \text{H} \cdot + e^-$	0.7559
$i\text{-C}_4\text{H}_{10} \longrightarrow i\text{-C}_4\text{H}_9^+ + \text{H} \cdot + e^- \text{ (planar)}$	0.7004
$\longrightarrow i\text{-C}_4\text{H}_9^+ + \text{H} \cdot + e^- \text{ (pyramidal)}$	0.7766
 $\longrightarrow \text{Cation} + \text{H} \cdot + e^-$	0.7299

for the bicyclo[1.1.1]pentane derivative is between that of the planar and pyramidal *t*-butyl cations. The results provide an explanation for the high reactivity of the bridgehead halides and for the formation of 3-methylenecyclobutanol as the product. Considerable charge is transferred to the 3 position as a result of

(7) A comparison of the reactivity in chlorination of bicyclo[1.1.1]pentane and other hydrocarbons will be presented subsequently.

(8) As might be expected based on our results with bicyclo[2.1.1]hexyl 5-tosylate<sup>9</sup> and bicyclo[3.1.1]heptyl 6-tosylate,<sup>10</sup> 2-chlorobicyclo[1.1.1]pentane is also quite reactive ( $k = 1.16 \times 10^{-3} \text{ sec}^{-1}$  at 100°). However, it is not as reactive as the 1-chloro derivative.

The data available at the present time suggest that the structure of the  $B_5H_5^-$  anion is not greatly different from that of  $B_5H_5$ . This interpretation is based on the presence of the high-field doublet in the  $^{11}B$  nmr spectrum, which is typical for "apex" type boron atoms, and on the facile reaction of the anion with HCl to regenerate  $B_5H_5$  at low temperatures. The asymmetry of the low-field group in the  $^{11}B$  nmr spectrum suggests that there are probably more than two types of "basal" boron atoms present. The exclusive formation of  $\mu$ -DB $_5$ H $_8$  in the reaction of LiB $_5$ H $_8$  with DCl suggests that the D $^+$  enters directly into a bridging position by a mechanism that requires minimal hydrogen rearrangement in the activated complex. These data may be interpreted in terms of three-center bond structures 2221 or 3130 suggested by Lipscomb,<sup>6</sup> though other possibilities cannot be excluded.

Further investigations of these and related systems are underway and will be reported shortly.

**Acknowledgment.** This work was supported in part by the National Science Foundation.

# On the Mechanisms of Formation and Decomposition of Benzocyclopropenes. Electron Spin Resonance Spectral and Chemical Evidence for Triplet State Diradical Intermediates<sup>1</sup>

Sir:

The extension of the synthesis of cyclopropenes from 3H-pyrazoles<sup>2</sup> to 3H-indazoles resulted in a convenient method for the preparation of benzocyclopropene derivatives.<sup>3</sup> For example, irradiation of the 3H-indazoles Ia-c in hydrocarbon solvents at low temperatures gave the benzocyclopropenes IIa-c in satisfactory yields. We now wish to report the identification of diradicals which are probable reaction intermediates in the formation and in the thermorearrangements of IIa-c.

Ultraviolet irradiation (Pyrex filter) of Ia-c in pentane-isopentane glasses at 77°K in the cavity of an esr spectrometer produced spectra which can be assigned unambiguously to molecules in triplet states. In addition to the  $\Delta m = 2$  transitions at half-field, six maxima were observed corresponding to the extreme values of the  $\Delta m = 1$  transitions with the magnetic field vector parallel to the principal magnetic axes of the molecules.<sup>4</sup> All transitions were fitted to the usual triplet

state spin Hamiltonian,  $\mathcal{H} = g \cdot H \cdot |\beta| S + DS_z^2 + E(S_x^2 - S_y^2)$ ;  $S = 1$ .<sup>5</sup> The zero-field splitting parameters for the spectra obtained from Ia-c are, respectively:  $D/hc$ ,  $0.1069 \pm 0.0005$ ,  $0.1110 \pm 0.0005$ ,  $0.1217 \pm 0.0008$  cm $^{-1}$ ;  $E/hc$ ,  $0.0058 \pm 0.0003$ ,  $0.0069 \pm 0.0003$ ,  $0.0066 \pm 0.0003$  cm $^{-1}$ . All  $g$  values are close to 2.002. The spectra produced from Ia and Ib persisted with undiminished intensities for several hours after irradiation had been discontinued, but disappeared rapidly on warming above 100°K. The spectrum obtained from Ic was considerably weaker and faded in less than 1 min after irradiation was ceased, even at 77°K.

The esr data strongly suggest the formation of triplet-state molecules with structure III in which one of the unpaired electrons is essentially localized in a  $\sigma$  orbital in the benzene ring plane, while the second electron is delocalized in the  $\pi$  system.<sup>6</sup> Extended Hückel calculations<sup>7</sup> on the corresponding benzyl radicals predict spin densities at the *ortho* positions of 9.2, 8.4, and 12.2% for IIIa-c, respectively. The observed  $D$  values are in semiquantitative agreement with these calculations. The one-center dipole-dipole interaction, represented in the carbene structure of III, makes a large contribution to the zero-field splitting.

A sample of Ib which had been irradiated in a glass at 77°K and which exhibited a strong esr spectrum was warmed up and analyzed for products. Benzocyclopropene IIb was identified, suggesting, but not proving, that IIIb cyclizes on warming.<sup>8</sup>

Chemical evidence for the intermediacy of diradicals of structure III in the photolysis of indazoles was obtained when Ia was photolyzed at -70° in butadiene. Two isomeric products were isolated in 60% yield in a ratio of 1.5:1 and were assigned structures Va and Vb on the basis of mass spectral (parent peak:  $m/e$  183.1045) and nmr evidence [resonances at  $\delta$  (TMS) Va, 1.33 s (3), 2.9 m (2), 3.3 m (1), 5.3 m (2), 5.9 m (1), 7.2 m (4); Vb, 1.64 s (3), 2.7 m (1), 3.0 m (2), 5.2 m (2), 6.1 m (1), 7.2 m (4)].<sup>9</sup>

were observable. The  $S/N$  ratio of the transitions corresponding to the orientation with the greatest line separation ( $H \parallel z$ ) was too small to determine the peak positions.

(5) For a discussion of esr spectra of triplet states see: C. A. Hutchison, Jr., and B. W. Mangum, *J. Chem. Phys.*, **34**, 908 (1961); E. Wasserman, L. C. Snyder, and W. A. Yager, *ibid.*, **41**, 1763 (1964).

(6) No evidence is at present available on the geometries of III. While it is highly likely that the molecules are planar, it is unknown whether the methyl group in III has a *syn* or *anti* relationship to the *ortho* radical site.

(7) R. Hoffmann, *J. Chem. Phys.*, **39**, 1397 (1963).

(8) The irradiated glasses were intensely yellow colored at 77°K and turned colorless on warming. Considering the close relationship of III with the corresponding benzyl radicals, it is very probable that the color is caused by III. The formation of III from I may well be a two-step process, proceeding through an *o*-quinoid diazo compound

(3) R. Anet and F. L. Anet, *ibid.*, **86**, 525 (1964); cf. G. L. Closs, *Advan. Alicyclic Chem.*, **1**, 64 (1966).

(4) In the spectrum obtained from Ic only four  $\Delta m = 1$  transitions

o trapping products were obtained with simple ns such as isobutylene. The latter observation and orientation of the butadiene addition suggest a two-mechanism with the possible intermediacy of the nance-stabilized diradical IV.

enzocyclopropenes Ia-c are unstable at room temperature. Ia decomposes mostly to polymeric material, gives 2-methoxy-3-methylbenzofuran and  $\alpha$ -carboxystyrene, while Ic forms quantitatively  $\alpha$ -oxystyrene. All these reactions can be visualized proceed through initial formation of diradicals of

III, formed by homolytic cleavage of the highly strained benzocyclopropene single bond. This hypothesis receives strong support from the observation of thermodecomposition of IIa in butadiene at 25° gives Va and Vb in approximately equal amounts. Similarly, the rearrangement of IIb can be intercepted by butadiene, yielding the corresponding indane derivatives VIa and VIb. The decomposition rates of IIa and IIb are not accelerated by butadiene, suggesting that a molecular ring opening precedes the fast addition

The assignment of stereochemistry of the adducts is based on chemical shifts only and should be considered tentative.

## Stereochemistry of Formation of Cyclooctatrienes Valence Isomerization

The continuing lively interest in the stereochemistry of valence isomerizations prompts us to report evidence concerning the stereochemistry of formation of cyclooctatrienes via a thermal valence isomerization.<sup>1</sup> Following the lead of Ziegenbein,<sup>2</sup> we have partially hydrogenated a sample of *trans*-2,*trans*-8-decadiene-4,6-diene (I), prepared by the method of Bohlmann and Ziegenbein,<sup>3</sup> over a Lindlar catalyst (2 moles of hydrogen up to 0°). The mixture of products obtained could be separated by thin layer chromatography, but (Carbowax 20M column at 115°) separated five types of products. In order of elution these were: (1) a mixture of overhydrogenated compounds (probably dienes), 9%; (2) *trans*-7,8-dimethyl-2,4-bi-

Earlier reports<sup>1,2</sup> of the formation of valence isomers from tetra- did not provide evidence either for the route of their formation or for the stereochemistry.

W. Ziegenbein, *Chem. Ber.*, **98**, 1427 (1965).

cyclo[4.2.0]octadiene (II), 50%;  $\lambda_{\text{max}}$  278 m $\mu$ ; nmr (ppm) multiplet (4 H) at 5.3-6.0, multiplet (1 H) at 2.8-3.2, multiplet (3 H) at 2.1-2.6, doublet (3 H) at 1.09 ( $J = 6.5$  cps), doublet (3 H) at 1.01 ( $J = 6.5$  cps); (3) deca-2,4,6-trienes, 13%;  $\lambda_{\text{max}}$  260, 268, and 278 m $\mu$ ; (4) deca-2,4,6,8-tetraene, 15%;  $\lambda_{\text{max}}$  311, 296, 284, and 274 (sh) m $\mu$ ; (5) unknown, 13%. This hydrogenation mixture was heated for 2 hr at 75° and then treated with dimethyl acetylenedicarboxylate at 100° for 15 hr under nitrogen. Pyrolysis of the oily adduct at 200° and removal of the volatile products in a stream of nitrogen gave *trans*-2,*trans*-4-hexadiene (57% based on the amount of I in the mixture),<sup>5</sup>  $\lambda_{\text{max}}$  227 m $\mu$ ; nmr (ppm) multiplet at 5.1-6.2, doublet at 1.7 ( $J = 6.5$  cps). The presence of two types of methine protons in a 3:1 ratio and of two nonequivalent methyl groups in the bicyclic diene, coupled with the isolation of a hexadiene with two equivalent methyls, provides reasonable evidence for the *trans* orientation of the methyl groups in the ring-closure product.

A sample of *cis*-2,*trans*-8-decadiene-4,6-diene,  $\lambda_{\text{max}}$  312.5, 293, 276, 261, 247, 237, 230, and 211 m $\mu$ ,<sup>7</sup> was prepared by Cadiot-Chodkiewicz coupling<sup>8</sup> and reduced over a Lindlar catalyst as described above. The mixture was analyzed by glpc and shown to contain ca. 45% of *cis*-7,8-dimethyl-2,4-bicyclo[4.2.0]octadiene,  $\lambda_{\text{max}}$  275 m $\mu$ ; nmr (ppm) singlet (4 H) at 5.63, broad multiplet (4 H) at 2.4-2.8, doublet (6 H) at 1.03 ( $J = 7.0$  cps). The mixture was treated with dimethyl acetylenedicarboxylate and the resultant material pyrolyzed as before. The major volatile product (68% of the volatile material) was *cis*-3,4-dimethylcyclobutene,<sup>6</sup>  $\lambda_{\text{max}}$  end absorption only; nmr (ppm) singlet (2 H) at 6.0, broad multiplet (2 H) at 2.8-3.2, doublet (6 H) at 1.0 ( $J = 7.0$  cps). A second fraction (22%) contained a mixture of hexadienes.

These experiments establish the stereochemistry of the ring-closure product for two separate cases. All attempts<sup>9</sup> to separate from the partial hydrogenation mixture and to identify directly the reactant which leads to the ring-closed product have so far proved unsuccessful. The following experiments were designed to provide indirect evidence about the mechanism of the formation of the bicyclic dienes. Partial hydrogenation of I at ca. -40° followed by glpc analysis of an aliquot indicated that 48% of II and ca. 37% of under- and overhydrogenated products were identified by the detector.<sup>10</sup> The main hydrogenation mixture was separated from the Lindlar catalyst in the cold and immediately completely hydrogenated over platinum oxide at ca. -40°. Analysis followed by preparative glpc separation and identification of the products

(5) D. A. Bak and K. Conrow, *J. Org. Chem.*, **31**, 3958 (1966).

(6) A conrotatory ring opening of the intermediary 3,4-dimethylcyclobutene is to be expected. R. E. K. Winter, *Tetrahedron Letters*, 1207 (1965), reports the *trans*-3,4-dimethylcyclobutene isomerizes to *trans*-2,*trans*-4-hexadiene at 175°.

(7) Extinction coefficients are not reported since this material was contaminated with about 10% of the di-*trans* isomer. Preparation of a pure sample is underway.

(8) See G. Eglinton and W. McCrae, "Advances in Organic Chemistry: Methods and Results," Vol. 4, Interscience Publishers, New York, N. Y., 1963, pp 253-274.

(9) Studies aimed at finding a substituted tetraene which will permit the isolation of the reactant are in progress.

(10) The peaks indicated by the glpc detector and identified after trapping do not, of course, prove that these materials were originally present in the mixture put on the column. In the present case the data described show clearly that the component of interest II was formed on the column.
